# 1 Matrix

## 1.1 Singular Value Decomposition

Singular Value Decomposition ([SVD](#))

[MLcoban.com](http://MLcoban.com)

# 2 Probabilities

For more examples, exercises with solutions, check:

- Bishop et al. (2006) [BN06]. Pattern Recognition and Machine Learning.

## 2.1 General

### 2.1.1 Basic Definitions

- If  $x$  is discrete:  $\sum_x p(x) = 1$  with  $\forall 0 \leq p(x) \leq 1$
- If  $x$  is continuous:  $\int p(x) dx = 1 \Rightarrow \exists$  a **Probability Density Function (pdf.)**

$p(x)$  can take any positive value, as long as  $\int p(x) dx = 1$   **NOTE:**  
: theoretically  $p(x) = 0, \forall x$

- Common types

Joint probability:  $p(x_i, y_i) = p(X = x_i, Y = y_i)$

Marginal probability:  $p(x_i) = p(X = x_i)$

Conditional probability:  $p(y_i|x_i) = p(Y = y_i|X = x_i)$

- Sum rule:  $\sum$  joint probability (prob.) = marginal prob.

$\Rightarrow$  Marginalization

– discrete variable:  $p(x) = \sum_y p(x, y)$

– continuous variable:  $p(x) = \int p(x, y) dy$

- Product rule: Product of marginal prob. and conditional prob. = joint prob.

### 2.1.2 Expectation

For variable  $x$ :  $\mathbb{E}[x] = \sum_x x.p(x) = \int p(x)x dx$

For function  $f(\cdot)$ :  $\mathbb{E}[f(x)] = \sum_x f(x).p(x) = \int p(x)f(x) dx$

### 2.1.3 Independence and Variability

- Independence. E.g.:  $x, y$  are independent, then

$$\begin{cases} p(x|y) = p(x) \\ p(y|x) = p(y) \end{cases} \Leftrightarrow p(x, y) = p(x) \cdot p(y)$$

- Variability

– variance: how much variability there is in  $f(x)$  around its mean value  $\mathbb{E}[f(x)]$

$$\text{var}[f] = \mathbb{E}[(f(x) - \mathbb{E}[f(x)])^2] = \mathbb{E}[f(x)^2] - \mathbb{E}[f(x)]^2$$

– covariance: for two random variables  $x, y$

$$\text{cov}[x, y] = \mathbb{E}_{x, y}[xy] - \mathbb{E}[x] \cdot \mathbb{E}[y]$$

– covariance matrix: if  $x, y$  are vectors

$$\begin{aligned} \text{cov}[\mathbf{x}, \mathbf{y}] &= \mathbb{E}_{\mathbf{x}, \mathbf{y}}[\{\mathbf{x} - \mathbb{E}[\mathbf{x}]\} \{\mathbf{y}^T - \mathbb{E}[\mathbf{y}^T]\}] \\ &= \mathbb{E}_{\mathbf{x}, \mathbf{y}}[\mathbf{x}\mathbf{y}^T] - \mathbb{E}[\mathbf{x}] \cdot \mathbb{E}[\mathbf{y}^T] \end{aligned}$$

### 2.1.4 Bayes Rule

$$\begin{aligned} p(x_i|y_i) \cdot p(y_i) &= p(y_i|x_i) \cdot p(x_i) = p(x_i, y_i) \\ \Rightarrow p(y_i|x_i) &= \frac{p(x_i|y_i) \cdot p(y_i)}{p(x_i)} = \frac{p(x_i|y_i) \cdot p(y_i)}{\sum_y p(x_i|y_i) \cdot p(y_i)} \end{aligned}$$

$\Rightarrow$  the Bayes equation:

$$\text{posterior} = \frac{\text{likelihood} \times \text{prior}}{\text{normalization factor}}$$

## 2.2 Types of Probability Distributions

Reference source: [machinelearningcoban.com](http://machinelearningcoban.com).

### 2.2.1 Bernoulli Distribution

Bernoulli Distribution is a distribution to describe binary discrete variables. It's the case that the variable can only take value in 2 classes  $x \in \{0, 1\}$ . E.g., the probability of throwing a coin. The Bernoulli distribution is defined with parameter  $\lambda \in [0, 1]$ :

$$p(x) = \text{Bern}_x[\lambda] = \begin{cases} p(x = 1) = \lambda \\ p(x = 0) = 1 - \lambda \end{cases} \quad (2.1)$$

In short form, the above equation can be combined into one:

$$p(x) = \lambda^x (1 - \lambda)^{(1-x)} \Rightarrow \begin{cases} p(0) = \lambda^0 (1 - \lambda)^1 = 1 - \lambda \\ p(1) = \lambda^1 (1 - \lambda)^0 = \lambda \end{cases} \quad (2.2)$$

### 2.2.2 Categorical Distribution

*Categorical Distribution* is the generalization of *Bernoulli Distribution* for  $K$  classes of the discrete variable  $x \in \{1, 2, \dots, K\}$ . Accordingly, there will be  $K$  parameters to describe this pdf:  $\lambda = [\lambda_1, \lambda_2, \dots, \lambda_K]$ , with  $\lambda_k \geq 0$  and  $\sum \lambda_k = 1$ . Each  $\lambda_k$  represents the probability to take the output  $k$ :  $p(x = k) = \lambda_k$ . In short:  $p(x) = \text{Cat}_x[\lambda]$ .

Another common way to represent the output is the one-hot vector,  $\mathbf{x} \in \{\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_K\}$  with  $\mathbf{e}_k$  is the  $k$ -unit vector, which has all 0-element, except the  $k$ -element equal to 1. E.g., given 3 classes:  $\mathbf{e}_1 = [1, 0, 0]^T$ ,  $\mathbf{e}_2 = [0, 1, 0]^T$ ,  $\mathbf{e}_3 = [0, 0, 1]^T$ . We will then have:

$$p(\mathbf{x} = \mathbf{e}_k) = \prod_{j=1}^K \lambda_j^{x_j} = \lambda_k \quad (2.3)$$

because for  $\mathbf{x} = \mathbf{e}_k$ , only  $x_k = 1$ , while  $x_j = 0, \forall j \neq k$ .

### 2.2.3 Univariate Normal Distribution

Univariate Normal Distribution is also known as the Gaussian distribution. For single dimension data (in 1D):  $x \in (-\infty, \infty)$ , the mean  $\mu \in \mathbb{R}$ , and the variance  $\sigma^2$  with  $\sigma \in \mathbb{R}$ .

$$p(x) = \text{Norm}_x[\mu, \sigma^2] = \mathcal{N}(\mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \cdot \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right) \quad (2.4)$$

**NOTE:**

- **Marginals prob. of Gaussian are again Gaussian.**
- When estimating the parameters (params.) of a Gaussian, beware the underestimation problem.

$$\begin{aligned} \mathbb{E}[\mu_{ML}] &= \mu \\ \mathbb{E}[\sigma_{ML}^2] &= \left(\frac{N-1}{N}\right) \sigma^2 \\ \Rightarrow \tilde{\sigma}^2 &= \left(\frac{N}{N-1}\right) \sigma_{ML}^2 = \frac{1}{N-1} \sum_{n=1}^N (x_n - \hat{\mu})^2 \end{aligned}$$

**Figure 2.1:** Bivariate Gaussian distribution ([src](#)).

### 2.2.4 Multivariate Normal Distribution

*Multivariate Normal Distribution* is the extension of *Univariate Normal Distribution* to multi-dimensional data:  $\mathbf{x}, \boldsymbol{\mu} \in \mathbb{R}^D, \sigma^2 \Rightarrow \Sigma \in \mathbb{S}_{++}^D$  ( $\mathbb{S}_{++}^D$  is the set of positive definite symmetric matrix)

$$p(x) = \text{Norm}_x[\boldsymbol{\mu}, \Sigma] = \mathcal{N}(\boldsymbol{\mu}, \Sigma) = \frac{1}{2\pi^{D/2} |\Sigma|^{\frac{1}{2}}} \cdot \exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu})^T \Sigma^{-1}(\mathbf{x} - \boldsymbol{\mu})\right) \quad (2.5)$$

### 2.2.5 Beta Distribution

This distribution describes the parameter for another distributions. E.g., Dirichlet [pdf](#). describes Categorical Distribution (Subsec. [2.2.2](#))

# 3 Information Theory

Again, for more examples, exercises with solutions, check:

- Bishop et al. (2006) [BN06]. Pattern Recognition and Machine Learning.

## 3.1 Entropy

$$p(\mathbf{x}) \quad \text{-- distribution (e.g. over observation } \mathbf{x}) \quad (3.1)$$

$$\mathcal{H}(p) = -\mathbb{E}_{\mathbf{x} \sim p(\mathbf{x})}[\log p(\mathbf{x})] \quad \text{-- entropy - how "broad" } p(\mathbf{x}) \text{ is} \quad (3.2)$$

$$= -\sum_{i=1}^N p(\mathbf{x}_i) \log p(\mathbf{x}_i) \quad (3.3)$$

Intuition:

- How *random* is the variable?  
The more random the variable, the higher the entropy (Fig. 3.1)
- How large is the log **prob.** in expectation *under* itself?
  - If you mostly see low log **prob.**, then there are many places with similar **prob.**, and the entropy, as negative log, would be high (Fig. 3.1a).
  - If you mostly see high log **prob.**, then the variable focuses around only a few place, thus, the entropy, as negative log, would be low (Fig. 3.1b).

(a) Example of  $p(x)$  with high entropy.

(b) Example of  $p(x)$  with low entropy.

**Figure 3.1:** Examples of  $p(x)$  with different entropy.

## 3.2 Cross Entropy

The cross entropy between two given **prob.** distributions  $p$  and  $q$  is defined as:

$$H(p, q) = \mathbb{E}_p[-\log q] \quad (3.4)$$

With  $\mathbf{p}, \mathbf{q}$  as discrete variables:

$$H(\mathbf{p}, \mathbf{q}) = \sum_{i=1}^C p_i \log q_i \quad (3.5)$$

**NOTE:**  $\nexists \log(0) \Rightarrow$  condition:  $\mathbf{q} > 0$

### 3.3 Kullback - Leiber Divergence

The Kullback–Leibler ([KL](#)) divergence, also known as ([a.k.a.](#)) *relative entropy*, tells:

- How *different* are two distributions?
- How small is the expected log [prob.](#) of one distribution under another, **minus entropy**?
- How many bits of info we expect to loose
- **A function** that we can **optimized**

Example reference: [countbayesie](#)

$$H = - \sum_{i=1}^N p(x_i) \log p(x_i) \quad (3.6)$$

$$D_{KL}(p||q) = \sum_{i=1}^N p(x_i) [\log p(x_i) - \log q(x_i)] \quad \text{discrete case} \quad (3.7)$$

$$= \sum_{i=1}^N p(x_i) \log \frac{p(x_i)}{q(x_i)} \quad (3.8)$$

$$= \mathbb{E}_{x \sim p(x)} [\log p(x) - \log q(x)] \quad (3.9)$$

$$D_{KL}(p||q) = - \int p(\mathbf{x}) \ln q(\mathbf{x}) d\mathbf{x} - \left( - \int p(\mathbf{x}) \ln p(\mathbf{x}) d\mathbf{x} \right) \quad \text{continuous case} \quad (3.10)$$

$$= - \int p(\mathbf{x}) \ln \frac{q(\mathbf{x})}{p(\mathbf{x})} d\mathbf{x} \quad (3.11)$$

$$D_{KL}(p||q) \geq 0 \quad (3.12)$$

$$D_{KL}(p||q) = 0 \iff p(\mathbf{x}) = q(\mathbf{x}) \quad (3.13)$$

**cross entropy = entropy + KL Divergence**

$$H(p, q) = H(p) + D_{KL}(p||q) \quad (3.14)$$

E.g.: KL divergence between two normal distributions  $\mathcal{N}(\mu_1, \sigma_1)$  and  $\mathcal{N}(\mu_2, \sigma_2)$ :

$$D_{KL}(p, q) = \log \frac{\sigma_2}{\sigma_1} + \frac{\sigma_1^2 + (\mu_1 - \mu_2)^2}{2\sigma_2^2} - \frac{1}{2} \quad (3.15)$$

**PSEUDO CODE:** with  $\mu_2 = 0, \sigma_2 = 1$

$$\mu, \sigma = \text{encoder}(\hat{x}) \quad (3.16)$$

$$z = \mu + \sigma * \text{random\_normal}(0, 1) \quad (3.17)$$

$$y = \text{decoder}(z) \quad (3.18)$$

$$\text{recon\_loss} = x.\log(y) + (1-x)\log(1-y) \quad (3.19)$$

$$\text{KL\_loss} = \frac{1}{2}[\mu^2 + \sigma^2 - \log(\sigma^2 + 1e^{-8}) - 1] \quad (3.20)$$

$$\text{ELBO} = \text{recon\_loss} - \text{KL\_loss} \quad (3.21)$$

$$\text{loss} = -\text{ELBO} \quad (3.22)$$

### 3.4 Mutual Information

$$p(x) \quad - \text{distribution (e.g. over observation } \mathbf{x}) \quad (3.23)$$

$$\mathcal{H}(p(\mathbf{x})) = -\mathbb{E}_{\mathbf{x} \sim p(\mathbf{x})}[\log p(\mathbf{x})] \quad - \text{entropy - how "broad" } p(\mathbf{x}) \text{ is} \quad (3.24)$$

$$\mathcal{I}(\mathbf{x}; \mathbf{y}) = D_{KL}(p(\mathbf{x}, \mathbf{y}) || p(\mathbf{x})p(\mathbf{y})) \quad - \text{mutual information} \quad (3.25)$$

$$= \mathbb{E}_{(\mathbf{x}, \mathbf{y}) \sim p(\mathbf{x}, \mathbf{y})} \left[ \log \frac{p(\mathbf{x}, \mathbf{y})}{p(\mathbf{x})p(\mathbf{y})} \right] \quad (3.26)$$

$$= \mathcal{H}(p(\mathbf{y})) - \mathcal{H}(p(\mathbf{y}|\mathbf{x})) \quad - \text{relates to IG} \quad (3.27)$$

The last equation implies that we can interpret mutual information  $\mathcal{I}(\mathbf{x}; \mathbf{y})$  as [IG](#), how much more do we know about  $\mathbf{y}$  after receiving observation about  $\mathbf{x}$ .

E.g.:

- If  $\mathbf{x}$  and  $\mathbf{y}$  are independent of each others, then  $p(\mathbf{x}, \mathbf{y}) = p(\mathbf{x})p(\mathbf{y})$ , thus  $\mathcal{I}(\mathbf{x}; \mathbf{y}) = 0$
- If  $\mathbf{x}$  and  $\mathbf{y}$  depends on each others more and more, the different between the joint [prob.](#)  $p(\mathbf{x}, \mathbf{y})$  and the product of marginal [prob.](#)  $p(\mathbf{x})p(\mathbf{y})$  grows, thus the  $\mathcal{I}(\mathbf{x}; \mathbf{y})$  is larger.

# 4 Convexity

## 4.1 Convex Sets

- Definition 1: line connects 2 points of a convex set lies within the set
- Definition 2:  $\mathcal{C}$  is a convex set if for  $\forall x_1, x_2 \in \mathcal{C}$ :

$$x_\theta = \theta x_1 + (1 - \theta)x_2 \in \mathcal{C}, \quad \forall 0 \leq \theta \leq 1$$

- Hyperplane is a convex set

$$a_1 x_1 + a_2 x_2 + \dots + a_n x_n = \mathbf{a}^T \mathbf{x} = b, \quad b, a_i \in \mathbb{R}, \quad i \in \mathbb{N}$$

- Half-space is a convex set

$$a_1 x_1 + a_2 x_2 + \dots + a_n x_n = \mathbf{a}^T \mathbf{x} \leq b, \quad b, a_i \in \mathbb{R}, \quad i \in \mathbb{N}$$

- Matrix  $A$  is positive definite if:

$$\mathbf{x}^T \mathbf{A} \mathbf{x} \geq 0, \quad \forall \mathbf{x} \in \mathbb{R}^n \iff \boxed{A \succ 0}$$

because  $\exists A^{-1} \Rightarrow \forall \lambda \neq 0$  (eigenvalues)

- Intersection of convex sets is a convex set  
 $\Rightarrow$  Polyhedra, which is the intersection of halfspaces and hyperplanes is convex.
- $x$  is said to be a convex combination of  $x_1, x_2, \dots, x_k$  if

$$x = \theta_1 x_1 + \theta_2 x_2 + \dots + \theta_k x_k \quad \text{with} \quad \theta_1 + \theta_2 + \dots + \theta_k = 1$$

- Convex hull of a set  $(x_1, x_2, \dots, x_k)$  is a set of all possible convex combination of that set.

**Convex hull of a set is the smallest convex set that contains that set.**

- Two convex sets  $\mathcal{C}$  and  $\mathcal{D}$  are disjoint then exist  $a, b$  such:

$$\begin{cases} \mathbf{a}^T \mathbf{x} \leq b & \forall \mathbf{x} \in \mathcal{C} \\ \mathbf{a}^T \mathbf{x} \geq b & \forall \mathbf{x} \in \mathcal{D} \end{cases}$$

Set of all  $\mathbf{x}$  that  $\mathbf{a}^T \mathbf{x} - b = 0$  is a hyperplane that separate  $\mathcal{C}$  and  $\mathcal{D}$

$\Rightarrow$  separating hyperplane

## 4.2 Convex function

Definition:  $f: \mathbb{R}^n \rightarrow \mathbb{R}$  is a convex function if the domain  $\text{dom}(f)$  is a convex set and:

$$f(\theta x + (1 - \theta)y) \leq \theta f(x) + (1 - \theta)f(y), \quad \forall x, y \in \text{dom}(f), \quad 0 \leq \theta \leq 1$$

- A function  $f$  is **strictly convex** if:

$$f(\theta x + (1 - \theta)y) < \theta f(x) + (1 - \theta)f(y)$$

If there is a minimum point that it is the only minimum point and a global minimum

- **Affine function:**  $f(\mathbf{x}) = \mathbf{a}^T \mathbf{x} + b$  is both convex and concave

If the variable is a matrix  $\mathbf{X}$ :  $f(\mathbf{X}) = \text{trace}(\mathbf{A}^T \mathbf{X}) + b$

- **Quadratic form:**  $f(\mathbf{x}) = \mathbf{x}^T \mathbf{A} \mathbf{x} + \mathbf{b}^T \mathbf{x} + c$  is
  - convex if  $A \succeq 0$
  - concave if  $-A \succeq 0$
- A function satisfies 3 norm conditions  $\Rightarrow$  convex
- $\alpha$ -subset level of  $f : \mathbb{R}^n \rightarrow \mathbb{R}$ :  $\mathcal{C}_\alpha = \{\mathbf{x} \in \text{dom} f \mid f(\mathbf{x}) \leq \alpha\}$

Checking if  $f$  is convex:

- First order condition if and only if (i.f.f.):  $\begin{cases} \text{differentiable with convex domain} \\ f(x) \geq f(x_0) + \nabla f(x_0)^T (x - x_0), \quad \forall x, x_0 \in \text{dom} f \end{cases}$
- Second order condition: the Hessian  $\nabla^2 f(x) \succeq 0$

# 5 Optimization

**Problem:**

$$\mathbf{x}^* = \arg \min_{\mathbf{x}} f_0(\mathbf{x}) \quad \text{subject to} \quad \begin{cases} f_i(\mathbf{x}) \leq 0, i = 1, 2, \dots, m & \text{(inequality constraints)} \\ h_j(\mathbf{x}) = 0, j = 1, 2, \dots, p & \text{(equality constraints)} \end{cases} \quad (5.1)$$

$$\text{feasible set } \mathcal{D} = \bigcap_{i=1}^m \text{dom} f_i \cap \bigcap_{j=1}^p \text{dom} h_j \Rightarrow \text{set of all } \mathbf{x} \text{ satisfying all constraints} \quad (5.2)$$

## 5.1 Convex Optimization Problem

**Problem:**

$$\mathbf{x}^* = \arg \min_{\mathbf{x}} f_0(\mathbf{x}) \quad (5.3)$$

$$\text{subject to} \quad \begin{cases} f_i(\mathbf{x}) \leq 0, i = 1, 2, \dots, m & \text{(inequality constraints)} \\ \mathbf{a}_j^T \mathbf{x} - b_j = 0, j = 1, 2, \dots, p & \text{(equality constraints)} \\ f_0 \text{ is convex func.} \\ f_i \text{ is convex func.} \\ h_j \text{ is affine func.} \end{cases} \quad (5.4)$$

$$\Rightarrow \begin{cases} f_i(x) \leq 0 \Rightarrow \text{0-sublevel set of } f_i \\ h_j(x) = 0, \quad \forall x \Rightarrow \text{hyperplane} \end{cases} \quad (5.5)$$

$\Rightarrow$  we optimize a convex function in a convex set domain.

## 5.2 Linear Programming

(Vietnamese: Quy hoạch tuyến tính)

**Problem:**

$$\mathbf{x}^* = \arg \min_{\mathbf{x}} \mathbf{c}^T \mathbf{x} + d \quad \text{subject to} \quad \begin{cases} \mathbf{G}\mathbf{x} \leq \mathbf{h} \\ \mathbf{A}\mathbf{x} = \mathbf{b} \end{cases} \quad (5.6)$$

A standard form of Linear Programming (LP):

$$\mathbf{x}^* = \arg \min_{\mathbf{x}} \mathbf{c}^T \mathbf{x} \quad \text{subject to} \quad \begin{cases} \mathbf{Ax} = \mathbf{b} \\ \mathbf{x} \leq \mathbf{0} \end{cases} \quad (5.7)$$

Python: `cvxopt.solvers.lp`

### 5.3 Quadratic Programming

**Problem:**

$$\mathbf{x}^* = \arg \min_{\mathbf{x}} \frac{1}{2} \mathbf{x}^T \mathbf{Px} + \mathbf{q}^T \mathbf{x} + r \quad \text{subject to} \quad \begin{cases} \mathbf{Gx} \leq \mathbf{h} \\ \mathbf{Ax} = \mathbf{b} \\ P \succeq 0 \quad (P \text{ is semi-definite}) \end{cases} \quad (5.8)$$

**NOTE:** When  $P = 0$ , Quadratic Programming (QP) is LP

Python: `cvxopt.solvers.qp`

### 5.4 Geometric Programming

- Function  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  with  $\text{dom} f = \mathbb{R}_{++}^n$  (all element  $> 0$ ) is a monomial function if:

$$f(x) = c x_1^{a_1} x_2^{a_2} \dots x_n^{a_n}, \quad c > 0, \quad a_i \in \mathbb{R} \quad (5.9)$$

- Function  $f$  is a posynomial function if:

$$f(x) = \sum_{k=1}^K c_k x_1^{a_{1k}} x_2^{a_{2k}} \dots x_n^{a_{nk}}, \quad c_k > 0 \quad (5.10)$$

**Problem:**

$$\mathbf{x}^* = \arg \min_{\mathbf{x}} f_0(\mathbf{x}) \quad \text{subject to} \quad \begin{cases} f_i(\mathbf{x}) \leq 1, & i = 1, 2 \dots m \\ h_j(\mathbf{x}) = 1, & j = 1, 2 \dots p \\ f_0, f_i \text{ are posynomial func.} \\ h_j \text{ are monomial func.} \end{cases} \quad (5.11)$$

$\Rightarrow$  geometric programming ( $x > 0$  is hidden)

$$\text{Set:} \quad \begin{cases} x_i = e^{y_i} \\ y_i = \log(x_i) \end{cases} \quad \Rightarrow f_0(\mathbf{x}) = \exp(\mathbf{a}^T \mathbf{y} + b)$$

Python: `cvxopt.solvers.gp`

# 6 Search Algorithms

**Search problem** is one common type of problem which has numerous presences in our lives. The well-known Travelling Salesman Problem (**TSP**) and its variants are search problems, in which the salesman have to find the shortest route that visit every cities. Many Reinforcement Learning (**RL**) problems can also be viewed as search problems, in which the machine find the most optimal plan to reach the goal.

A search problem consists of: an agent in a state space, a successor function, a start state and a goal state. The **agent** is the one taking the **action**, e.g., in **TSP**, the agent is the salesman, and the action is to travel; in **RL**, the agent is the robot or the machine, and the action could be to move to a different position. The **search state** represents the current situation that the agent is in, which would not necessary equivalent to the world state, which includes every possible details about the environment. E.g., in **TSP**, the state is the current city, every time the action traveling is taken, the agent moves from one city to another (one state to another). The **successor function** describes the transition from one state to another. This function usually comes with the transition action and costs.

A **solution of search problem** is a sequence of actions (a plan) which transform the start state to a goal state. **Search algorithms** find search solutions, which can be optimal, but in many practical cases, close to optimal within time limitation.

This chapter structures as follows:

- The first section describes how a search problem is formulated mathematically as a graph.
- The second section presents some well-known search algorithms.

## 6.1 Graph

A graph is the mathematical representation of a search problem. A graph consists of nodes and edges.

6.1.1 Undirected Graph

6.1.2 Directed Graph

6.1.3 Adjacency Matrix

6.1.4 Incidence Matrix

6.1.5 Trees and Forest

6.2 Search Algorithms

6.2.1 Properties

6.2.2 Depth-first search

6.2.3 Breadth-first search

6.2.4 Prim's Algorithm

6.2.5 Kruskal's Algorithm

6.2.6 Dijkstra's Algorithm

6.2.7 Bellman and Ford's Algorithm

6.2.8 A\* Algorithm

[TODO: ]

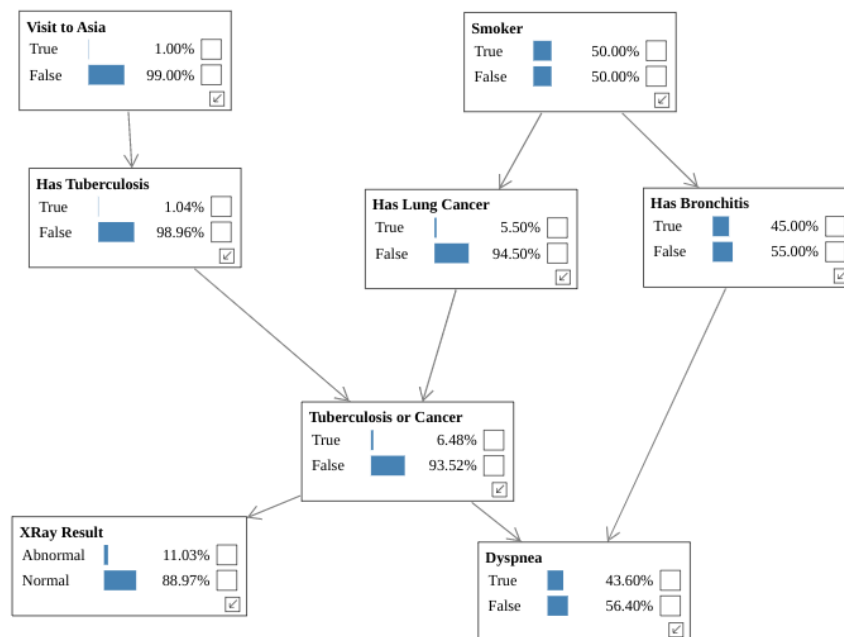

# 7 Graphical Models

For more examples, exercises with solutions, check:

- Bishop et al. (2006) [BN06]. Pattern Recognition and Machine Learning.

## 7.1 Bayesian Network

Bayesian networks, [a.k.a.](#), Bayes nets, Belief networks and sometimes Causal networks, are graphical representation of a probabilistic model. It comprises of nodes and directed edges

**Figure 7.1:** Example of Bayesian network: the Asia network ([src](#)).

They are useful in a variety of tasks

- Descriptive analytic
- Diagnostic analytic
- Predictive analytic
- Prescriptive analytic
