# 1 Overview

This is my learning notes for RL. RL are approaches for learning decision making from experience. In the Artificial Intelligence (AI) context, many RL algorithms handle the scarcity of available (human-annotated) data.

*Instead of trying to produce a program to simulate the adult mind, why not rather try to produce one which simulates the child's? If this were then subjected to an appropriate course of education, one would obtain the adult brain. - Alan Turing -*

A RL problem has 3 major blocks as follows:

**Figure 1.1:** Structure of RL algorithms.

## 1.1 Learning resources

- Deep RL - CS285, UC Berkeley - Sergey Levine
- CS188 Berkeley AI
- The book *Reinforcement learning: An introduction* [SB18]
- TensorFlow Agents' tutorial
- A Free course in Deep RL

## 1.2 Terminology & Notation

- Check out Markov Decision Process (MDP) and Partially Observable Markov Decision Process (POMDP) in the robotic notes or the RL book by Sutton and Barto (2018) [SB18].

## 1 Overview

- $\mathbf{s}_t$  - state
- $\mathbf{o}_t$  - observation
- $\mathbf{a}_t$  - action
- $\pi_\theta(\mathbf{a}_t|\mathbf{o}_t)$  - policy (or  $\pi_\theta(\mathbf{a}_t|\mathbf{s}_t)$  for fully observed scenario)
- $r(\mathbf{s}_t, \mathbf{a}_t)$  - reward or  $c(\mathbf{s}_t, \mathbf{a}_t)$  - cost
- $\tau$  - trajectory (as sequence of states and actions)

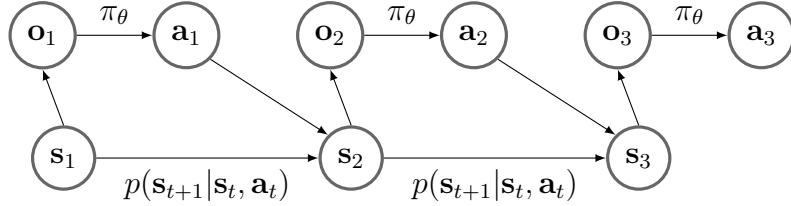

$$p_\theta(\tau) = p_\theta(\mathbf{s}_1, \mathbf{a}_1, \dots, \mathbf{s}_T, \mathbf{a}_T) = p(\mathbf{s}_1) \prod_{t=1}^T \pi_\theta(\mathbf{a}_t|\mathbf{s}_t) p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t)$$

- The Q-function is the expectation of total reward, from the q-state  $(\mathbf{s}_t, \mathbf{a}_t)$ , under policy  $\pi_\theta$ .

$$Q^\pi(\mathbf{s}_t, \mathbf{a}_t) = \sum_{t'=t}^T \mathbb{E}_{\pi_\theta} [r(\mathbf{s}_{t'}, \mathbf{a}_{t'})|\mathbf{s}_t, \mathbf{a}_t] \quad (1.1)$$

- The value function is the expectation of total reward, from the state  $\mathbf{s}_t$ , under policy  $\pi_\theta$ .

$$V^\pi(\mathbf{s}_t) = \sum_{t'=t}^T \mathbb{E}_{\pi_\theta} [r(\mathbf{s}_{t'}, \mathbf{a}_{t'})|\mathbf{s}_t] = \mathbb{E}_{\mathbf{a}_t \sim \pi(\mathbf{a}_t|\mathbf{s}_t)} Q^\pi(\mathbf{s}_t, \mathbf{a}_t) \quad (1.2)$$

**Figure 1.2:** The relationship between state  $\mathbf{s}_t$ , observation  $\mathbf{o}_t$  and action  $\mathbf{a}_t$ .

### 1.3 Overview on RL Algorithms

RL problem revolves around maximizing the expectation of total rewards. We aim to find the parameters (params.) to maximize the expected value of the sum of rewards, under the trajectory distribution.

$$\theta^* = \arg \max_{\theta} \mathbb{E}_{\tau \sim p_\theta(\tau)} \left[ \sum_t r(\mathbf{s}_t, \mathbf{a}_t) \right] \quad (1.3)$$

There are many methods / algorithms with their trade-offs and assumptions:

- Sampling efficiency & stability and ease of use
- Stochastic or deterministic
- Continuous or discrete
- Episode or infinite horizon

Tab. 1.1 gives an overview and comparison between algorithms.

## 1.4 Current State of the Art

Some current state of the art (**SOTA**) **RL** algorithms (**algor.**)s are:

- Deep Q-learning (**DQN**): model-free **RL** for discrete action spaces [**MKS+15**]
- Deep Deterministic Policy Gradients (**DDPG**): model-free **RL** for continuous action spaces [**LHP+15**]

## 1.5 Challenges

- Humans can learn incredibly quickly
- Humans can reuse past knowledge  
Transfer learning in Deep **RL** is an open problem
- Not clear what the reward function should be
- Not clear what the role of prediction should be

	Model-based	Value function fitting	Actor-critic	Policy Gradient
<b>Sample efficiency</b> (How many samples do we need to get good policy?)	<b>more efficient (fewer samples)</b> model-based shallow RL model-based deep RL	Off-policy ← → On-policy off-policy Q-learning actor-critic style	On-policy policy gradient	<b>less efficient (more samples)</b> Evolutionary or grad-free algor.
		- Sometimes, with simulated experiences, we can use <b>less efficient</b> algor. <b>Wall clock time ≠ efficiency</b> - More assumptions, as we go to the left		
<b>Stability &amp; ease of use</b> - Does it converge? - If yes, to what? - Does it <b>always</b> converge?	<b>RL is often not GD</b> Model will converge. <b>BUT</b> , better model do <b>NOT GUARANTEE</b> better policy	Minimize error of fit At worst case, doesn't optimize anything. Un-provable convergence ⇒ <b>more like heuristics</b>		<b>is GD</b> least efficient + assumptions
<b>Assumption</b>	By some: episode learning	<b>Generally:</b> full observability. By some continuous method: continuity / smoothness		By pure policy gradient methods: <b>Often:</b> episode learning
<b>Example</b>	- Dyna - Guided policy search	- Q-learning - DQN - Temporal difference - Fitted value iteration	- A3C [MBM+16] - SAC [HZA+18]	- REINFORCE [Wil92] - Natural policy gradient [Kak01] - Trusted Region policy optimization [SLA+]

Table 1.1: Different RL algorithms.

# 2 Markov Decision Process

## 2.1 Markov Chain

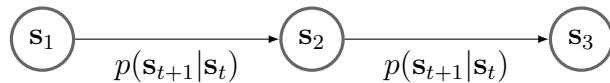

A Markov Chain  $\mathcal{M}$  is a tuple consisting of:

$$\mathcal{M} = \{\mathcal{S}, \mathcal{T}\}$$

$\mathcal{S}$  – state space  $s \in \mathcal{S}$  (discrete or continuous)

$\mathcal{T}$  – transition operator  $p(s_{t+1}|s_t)$  or  $\vec{\mu}_{t+1} = \mathcal{T}\vec{\mu}_t$  ( $\mathcal{T}$  is a matrix)

Markov chain is a process **without memories**. In other words, the next state  $s_{t+1}$  depends only on the current state  $s_t$ , not the previous state  $s_{t-1}$ .

## 2.2 Hidden Markov Model

A Markov chain becomes a Hidden Markov Model (HMM) when the states are not completely observable.

## 2.3 Markov Decision Process (MDP)

A MDP  $\mathcal{M}$  is a tuple consisting of:

$$\mathcal{M} = \{\mathcal{S}, \mathcal{A}, \mathcal{T}, r, \gamma\}$$

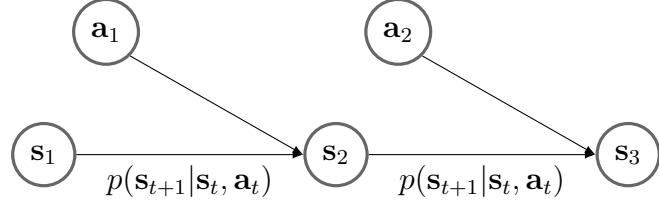

$\mathcal{S}$  – state space  $s \in \mathcal{S}$  (discrete or continuous)

$\mathcal{A}$  – action space  $a \in \mathcal{A}$  (discrete or continuous)

$\mathcal{T}$  – transition operator  $p(s_{t+1}|s_t)$  (now a tensor)

$r$  – reward function  $r : \mathcal{S} \times \mathcal{A} \rightarrow \mathbb{R}$ ,  $r(s_t, a_t)$

$\gamma$  – discount factor  $\gamma \in [0, 1]$  (optional)

There are definitions relating to MDP:

- Policy: choice of action (at each state):  $\pi_\theta(\mathbf{a}_t|\mathbf{s}_t)$
- Utility: sum of (discounted) rewards

A MDP can also be considered as a Markov chain on the augmented state  $(\mathbf{s}, \mathbf{a})$ , also known as (a.k.a.) Q-state. Knowing the state transition  $p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t)$  and policy  $\pi_\theta(\mathbf{a}_t|\mathbf{s}_t)$ , the transition of these Q-states can be derived as follows:

$$p((\mathbf{s}_{t+1}, \mathbf{a}_{t+1}) | (\mathbf{s}_t, \mathbf{a}_t)) = p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t)\pi_\theta(\mathbf{a}_{t+1}|\mathbf{s}_{t+1}) \quad (2.1)$$

MDP state projects an expectimax-like search tree [TODO: add image]

**NOTE:** Solving a MDP means to find a policy that maximize the received reward.

## 2.4 Partially Observable Markov Decision Process (POMDP)

A POMDP  $\mathcal{M}$  is a tuple consisting of:

$$\mathcal{M} = \{\mathcal{S}, \mathcal{A}, \mathcal{O}, \mathcal{T}, \mathcal{E}, r, \gamma\}$$

$\mathcal{S}$  – state space  $s \in \mathcal{S}$  (discrete or continuous)

$\mathcal{A}$  – action space  $a \in \mathcal{A}$  (discrete or continuous)

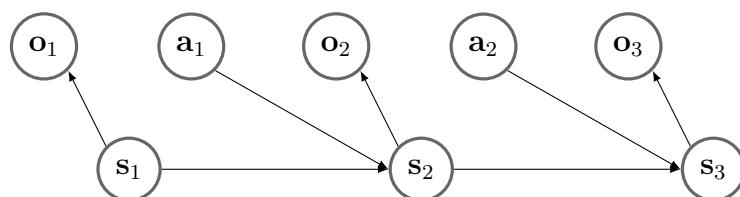

$\mathcal{O}$  – observation space  $o \in \mathcal{O}$  (discrete or continuous)

$\mathcal{T}$  – transition operator  $p(s_{t+1}|s_t)$

$\mathcal{E}$  – emission prob.  $p(o_t|s_t)$

$r$  – reward function  $r : \mathcal{S} \times \mathcal{A} \rightarrow \mathbb{R}$

$\gamma$  – discount factor  $\gamma \in [0, 1]$  (optional)

Finite versus (vs.) infinite horizon: [TODO: ]

### To solve infinite utilities:

- Finite horizon
- Discounting
- Absorbing state (like the fire hole, overheating)

POMDP is defined with a tuple:  $\langle S, A, O, P, R, Z, \gamma \rangle$ :

- $S$ : state
- $A$ : action
- $O$ : **observation**
- $P$ : transition matrix
- $R$ : reward
- $Z$ : **observation function (func.)**
- $\gamma$ : discount factor (optional)

$$Z_{s'o}^a = P [O_{t+1} = o | S_{t+1} = s', A_t = a] \quad (2.2)$$

$$\Rightarrow \begin{cases} V^*(b) \leftarrow \max_a \left[ R_b^a + \gamma \sum_{s'} P_{bb'}^a V(b') \right] \\ \pi^*(b) = \arg \max_a \left[ R_b^a + \gamma \sum_{s'} P_{bb'}^a V(b') \right] \end{cases} \quad (2.3)$$

Markov Models	Do we have control over the state transition?	
	No	Yes
Are the states completely observable?	Yes	Markov Chain
	No	HMM
		POMDP

## 2.5 Bellman equations

- $T(s, a, s') = P(s'|s, a)$  the prob. of reaching state  $s'$  from taking action  $a$  at state  $s$
- $R(s, a, s')$  the reward of making the transition
- $Q^*(s, a)$ : expected utility starting in state  $s$  and having taken action  $a$ , then act optimally

$$Q^*(s, a) = \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')] \quad (2.4)$$

It is the sum over possible next state  $s'$ , because there is uncertainty of which state  $s'$  will be reached, even with the same starting state  $s$  and action  $a$ .

- $V^*(s)$ : value of a state - expected utility starting in state  $s$  and acting optimally

$$V^*(s) = \max_a Q^*(s, a) \quad (2.5)$$

$$\Rightarrow V^*(s) = \max_a \sum_{s'} T(s, a, s') [R(s, a, s') + \gamma V^*(s')] \quad (2.6)$$

## 2 Markov Decision Process

- $\pi^*(s)$ : optimal action / policy from state  $s$

[TODO: Explain this??]

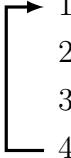

$$\mathbf{V}(\mathbf{s}) = \mathbb{E}[\mathbf{G}_t | \mathbf{S}_t = \mathbf{s}] = \mathbb{E} [\mathbf{R}_{t+1} + \gamma \mathbf{V}(\mathbf{S}_{t+1}) | \mathbf{S}_t = \mathbf{s}] = \mathbf{R}_s + \gamma \sum_{\mathbf{s}'} \mathbf{P}_{\mathbf{s}\mathbf{s}'} \mathbf{V}(\mathbf{s}') \quad (2.7)$$

# 3 Imitation Learning

Imitation Learning ([IL](#)), **a.k.a.** *Behavior Cloning*, Learning from Demonstration ([LfD](#)), essentially, this is **supervised learning**. One problem might arise: applying the learned policy  $\pi_\theta$  might lead to different action  $\mathbf{a}_t$ , which then leads to different observations and states, comparing to the given dataset:  $p_{data}(\mathbf{o}_t) \neq p_{\pi_\theta}(\mathbf{o}_t)$ . This **distribution mismatch** can be tackled by adding on-policy data.

## 3.1 DAgger

Dataset Aggregation ([DAgger](#)) aggregates training data from  $p_{\pi_\theta}(\mathbf{o}_t)$  instead of just  $p_{data}(\mathbf{o}_t)$ . Without [DAgger](#), it is proven that the error will grow quadratically with the number of time steps  $\mathcal{O}(\epsilon T^2)$ . [[RGB11](#)]

- 
1. Train  $p_{\pi_\theta}(\mathbf{o}_t)$  from human data  $\mathcal{D} = \{(\mathbf{o}_t, \mathbf{a}_t)_i\}$
  2. Run  $p_{\pi_\theta}(\mathbf{o}_t)$  to get data set  $\mathcal{D}_\pi = \{\mathbf{o}_1, \dots, \mathbf{o}_M\}$
  3. Ask human to label  $\mathcal{D}_\pi$  with action  $\mathbf{a}_t$
  4. Aggregate  $\mathcal{D} \leftarrow \mathcal{D} \cup \mathcal{D}_\pi$

The major problem with [DAgger](#) is that it requires human input again in step 3.

### **3.1.1 Recap**

- Requires human to annotate the data
- Often (but not always) insufficient by itself (distribution mismatch problem)
- Sometimes works well

#### **Problems:**

- Non-Markovian behavior
- Multimodal behavior

#### **Solutions:**

- Output a mixture of Gaussians
- Latent variable models
- Auto-regressive discretization ([src](#))

## 3.2 Visual Imitation Learning

### 3.2.1 Problem Formulation

**Problem setting:** given third-person-view images, output sequence of agent actions.

$$O_{human} = \{o_{h,0}, o_{h,1}, \dots, o_{h,T}\} \quad \text{Input: sequence of visual observations} \quad (3.1)$$

$$A_{robot} = \{a_{r,0}, a_{r,1}, \dots, a_{r,T}\} \quad \text{Output: sequence of agent actions} \quad (3.2)$$

### 3.2.2 Data Collection

- Kinesthetic teaching: tedious, time consuming labor work. [TMK16]
- Human teleoperation: expensive and/or complex, but possibly with large amount of rich and scalable data [ZMJ+18]
- Demonstration using assistive tools: is simple but works with one specific end-effector (EE) at a time [YGT+20]

**Figure 3.1:** Different data collection approaches for visual imitation learning.

### 3.2.3 Third Person Visual Imitation

Sharma et al. (2019) [SPG19]. “*Third-person Visual Imitation Learning via Decoupled Hierarchical Controller*”.

- The high-level sub-goal generator  $f_H$ : produces sequence of images, as visual sub-goals, from the images of expert demonstrations

$$f_H : \mathcal{O}_{rob} \times \mathcal{O}_h \times \mathcal{O}_h \rightarrow \mathcal{O}_{rob} \quad \begin{array}{l} \mathcal{O}_{rob} \text{ -- robot observation space} \\ \mathcal{O}_h \text{ -- human observation space} \end{array} \quad (3.3)$$

$$f_H(o_{r,t}, o_{h,t}, o_{h,t+k}) = o_{r,t+k} \quad \begin{array}{l} o_{r,t} \text{ -- robot observation at time } t \\ o_{h,t} \text{ -- human observation at time } t \end{array} \quad (3.4)$$

- The low-level controller  $\pi_L$ : produces action plans from the visual sub-goals

$$\begin{aligned} \pi_L : \mathcal{O}_{rob} \times \mathcal{O}_{rob} &\rightarrow \mathcal{A}_{rob} \\ \mathcal{O}_{rob} &\text{—robot observation space} \\ \mathcal{A}_{rob} &\text{—robot action space} \end{aligned} \tag{3.5}$$

$$\begin{aligned} \pi_L(o_{r,t}, o_{r,t+k}) &= a_{r,t} \\ o_{r,t} &\text{—robot observation at time } t \\ a_{r,t} &\text{—robot action at time } t \end{aligned} \tag{3.6}$$

**Limitations:** All limitations are probably due to the fact that the authors tried to formulate their goal-generator using the image-to-image translation model **pix2pix** ([github repo](#)).

- The view points for third-person-view and the robot’s first-person-view are **fixed**.
- Even comparing to pix2pix, they have a very strange formulation (personal opinion)
- Generate **low-quality** goal images
- Tried, then use "**bad**" loss functions ( $\mathcal{L}1, \mathcal{L}2$  loss, Structural Similarity Index (**SSIM**))
- Both high-level and low-level controllers required **kinesthetic** data collection.
- It might also be simpler using optical flow.
- Unclear about the baselines comparisons??

### 3.2.4 One-Shot Visual Imitation Learning with Meta-learning

[TODO: ??] Finn et al. (2017) [[FYZ+17](#)]. “One-shot Visual Imitation Learning via Meta-Learning”.

### 3.2.5 Others

There are many works on robotic visual imitation learning. This subsection summarizes their ideas.

- Improving generalization with:
  - Transformer / Attention network [[DG20](#)]
  - Domain randomization [[ZAB21](#)]
  - Multi-task, instead of one task with many variations [[MLL+22](#)]

### 3.2.6 Proposal

Perhaps the only way to be able to work with diverse view points and diverse **EE** tools is to formulate interactions with a graph, and with a library of motor primitives for that specific **EE**.

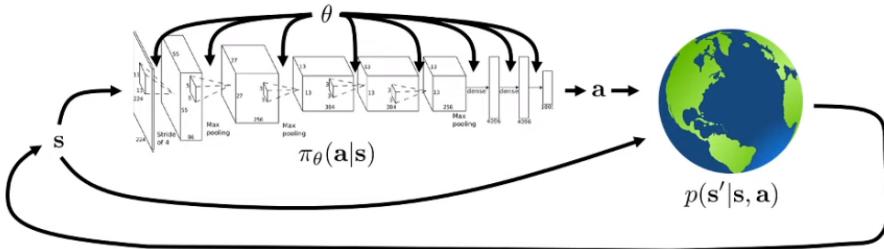

### 3 Imitation Learning

#### 3.2.7 References

# 4 Policy Gradient

The Policy Gradient is a model-free RL approach. A model-free RL approach assumes that we don't know the transition model  $p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t)$  or the initial state prob.  $p(\mathbf{s}_1)$ . However, we can either interact with the real world or run simulation to sample the data. With regard to the general structure for a RL algorithm, this approach has a neural network (Fig. 4.1) to learn and optimize the policy (the blue box in Fig. 1.1).

**Figure 4.1:** The policy network  $\pi_\theta(\mathbf{a}|\mathbf{s})$  with params.  $\theta$ . The network takes the current state  $\mathbf{s}_t$  as input, learn the policy  $\pi_\theta(\mathbf{a}_t|\mathbf{s}_t)$  by optimizing params.  $\theta$ , and output the action  $\mathbf{a}_t$ .

## 4.1 Approach

**Goal:** to maximize the expectation of total rewards, which will be denoted as  $J(\theta)$

$$\tau = \{\mathbf{s}_1, \mathbf{a}_1, \dots, \mathbf{s}_T, \mathbf{a}_T\} \quad - \text{denotes the trajectory} \quad (4.1)$$

$$p_\theta(\tau) = p_\theta(\mathbf{s}_1, \mathbf{a}_1, \dots, \mathbf{s}_T, \mathbf{a}_T) \quad - \text{prob. of the trajectory} \quad (4.2)$$

$$= p(\mathbf{s}_1) \prod_{t=1}^T \pi_\theta(\mathbf{a}_t|\mathbf{s}_t) p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t) \quad (4.3)$$

$$\theta^* = \arg \max_{\theta} \mathbb{E}_{\tau \sim p_\theta(\tau)} \left[ \sum_t r(\mathbf{s}_t, \mathbf{a}_t) \right] = \arg \max_{\theta} J(\theta) \quad - \text{RL goal} \quad (4.4)$$

$$= \arg \max_{\theta} \mathbb{E}_{(\mathbf{s}, \mathbf{a}) \sim p_\theta(\mathbf{s}, \mathbf{a})} [r(\mathbf{s}, \mathbf{a})] \quad - \text{infinite horizon case} \quad (4.5)$$

$$= \arg \max_{\theta} \sum_{t=1}^T \mathbb{E}_{(\mathbf{s}_t, \mathbf{a}_t) \sim p_\theta(\mathbf{s}_t, \mathbf{a}_t)} [r(\mathbf{s}_t, \mathbf{a}_t)] \quad - \text{finite horizon case} \quad (4.6)$$

$$J(\theta) = \mathbb{E}_{\tau \sim p_\theta(\tau)} \left[ \sum_{t=1}^T r(\mathbf{s}_t, \mathbf{a}_t) \right] \quad (4.7)$$

$$= \mathbb{E}_{\tau \sim p_\theta(\tau)} [r(\tau)] = \int p_\theta(\tau) r(\tau) d\tau \quad (4.8)$$

## 4 Policy Gradient

Even though we do not know the initial state [prob.](#)  $p(\mathbf{s}_1)$  and the transition model  $p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t)$ , we do have the ability to interact with the world and take samples from it. Thus, we can simply take  $N$  trajectory samples  $\tau_i$  and take the average of them to approximate the expectation of  $J(\theta)$ . The higher the number of sample trajectories  $N$  is, the better the approximation accuracy.

$$J(\theta) \approx \frac{1}{N} \sum_i^N \sum_t^T r(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) \quad \text{sum over samples and time steps} \quad (4.9)$$

Using a convenient identity transformation, we can derive [the Policy Gradient](#):

$$\nabla_\theta p_\theta(\tau) = p_\theta(\tau) \frac{\nabla_\theta p_\theta(\tau)}{p_\theta(\tau)} = p_\theta(\tau) \nabla_\theta \log p_\theta(\tau) \quad [\text{Wil92}] \quad (4.10)$$

$$\Rightarrow \nabla_\theta J(\theta) = \int \nabla_\theta p_\theta(\tau) r(\tau) d\tau = \int p_\theta(\tau) \nabla_\theta \log p_\theta(\tau) r(\tau) d\tau \quad (4.11)$$

$$= \mathbb{E}_{\tau \sim p_\theta(\tau)} [\nabla_\theta \log p_\theta(\tau) r(\tau)] \quad (4.12)$$

$$= \mathbb{E}_{\tau \sim p_\theta(\tau)} \left[ \left( \sum_{t=1}^T \nabla_\theta \log \pi_\theta(\mathbf{a}_t | \mathbf{s}_t) \right) \left( \sum_{t=1}^T r(\mathbf{s}_t, \mathbf{a}_t) \right) \right] \quad (\text{substitute Eq. 4.3}) \quad (4.13)$$

$$\boxed{\nabla_\theta J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \left[ \left( \sum_{t=1}^T \nabla_\theta \log \pi_\theta(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \right) \left( \sum_{t=1}^T r(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) \right) \right]} \quad (4.14a)$$

$$\Rightarrow \theta \leftarrow \theta + \alpha \nabla_\theta J(\theta) \quad (4.14b)$$

**REMARKS:** some what like Maximum Likelihood Estimation ([MLE](#)), makes good stuff happen more, bad stuff happens less

## 4.2 Partial Observability

$$\nabla_\theta J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \left[ \left( \sum_{t=1}^T \nabla_\theta \log \pi_\theta(\mathbf{a}_{i,t} | \mathbf{o}_{i,t}) \right) \left( \sum_{t=1}^T r(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) \right) \right]$$

$$\mathbf{o}_{i,t} \rightarrow \text{network} \rightarrow \mathbf{a}_{i,t}$$

$$\pi_\theta(\mathbf{a}_{i,t} | \mathbf{o}_{i,t})$$

Markov property is not actually used!  $\Rightarrow$  can use policy gradient for [POMDPs](#) without modification

## 4.3 High Variance Problem

In general, when we add a constant (either positive or negative) to the rewards, the policy should be the same. However, this is not the case for the above derivation of policy gradient.

The change of policy distribution varies depends on the value of the total rewards  $r(\tau)$ . In other words, the problem is **HIGH VARIANCE with  $r(\tau)$** .

- Different samples  $\Rightarrow$  different gradient estimate
- For a small finite number of (no.) samples  $\Rightarrow$  noisy gradient  
(At the beginning, policy  $\theta$  is not so good  $\Rightarrow$  random action  $\Rightarrow$  the not-so-good action results accumulate  $\Rightarrow$  high variance in the end)

**Solution:** reducing variance

- *Causality*: policy at later time step  $t'$  cannot affect reward at previous time step  $t$  ( $t' > t$ )

$$\Rightarrow \nabla_{\theta} J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \left[ \left( \sum_{t=1}^T \nabla_{\theta} \log \pi_{\theta}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \right) \left( \sum_{t'=t}^T r(\mathbf{s}_{i,t'}, \mathbf{a}_{i,t'}) \right) \right] \quad (4.15)$$

$$\approx \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_{\theta} \log \pi_{\theta}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \hat{Q}_{i,t} \quad (4.16)$$

This leads to smaller variance, because  $\hat{Q}_{i,t}$  (the reward to-go) is smaller than the total rewards, and the expectation of smaller number has smaller variance. [SMS+99; BB01]

- *Baselines*: the average of total rewards over different trajectories. It is proven that subtracting the baseline is unbiased in expectation. This is not the optimal baseline to reduce the variance, but it's simple and good enough.

$$b = \frac{1}{N} \sum_{i=1}^N r(\tau) \quad (4.17)$$

$$\nabla_{\theta} J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \nabla_{\theta} \log \pi_{\theta}(\tau) [r(\tau) - b] \quad (4.18)$$

$$r(\tau) - b = Q^{\pi}(\mathbf{s}_t, \mathbf{a}_t) - V^{\pi}(\mathbf{s}_t) \quad (4.19)$$

The complex optimal baselines are derived for each element  $g_i$  of the gradient  $\mathbf{g}$  [PS08]

$$b_h = \frac{\frac{1}{N} \sum_{i=1}^N \left[ \left( \sum_{t=1}^T \nabla_{\theta_h} \log \pi_{\theta}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \right)^2 r(\tau) \right]}{\frac{1}{N} \sum_{i=1}^N \left[ \left( \sum_{t=1}^T \nabla_{\theta_h} \log \pi_{\theta}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \right)^2 \right]} \quad (4.20)$$

## 4.4 Off-policy Policy Gradient

Since we have  $\tau \sim p_{\theta}(\tau)$ , vanilla Policy Gradient is on-policy. This poses a problem, since the neural networks change only a bit with each gradient step. Off-policy Policy Gradient can be derived with **Important sampling**.  $\theta'$  is the *new params*. and  $\theta$  is the *old params*.

## 4 Policy Gradient

$$\mathbb{E}_{x \sim p(x)}[f(x)] = \mathbb{E}_{x \sim q(x)} \left[ \frac{p(x)}{q(x)} f(x) \right] \quad (4.21)$$

$$\Rightarrow \nabla_{\theta'} J(\theta') = \mathbb{E}_{\tau \sim p_{\theta}(\tau)} \left[ \frac{\nabla_{\theta'} p_{\theta'}(\tau)}{p_{\theta}(\tau)} r(\tau) \right] \quad (4.22)$$

$$= \mathbb{E}_{\tau \sim p_{\theta}(\tau)} \left[ \frac{p_{\theta'}(\tau)}{p_{\theta}(\tau)} \nabla_{\theta'} \log p_{\theta'}(\tau) r(\tau) \right] \quad (4.23)$$

$$\approx \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \frac{\pi_{\theta'}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t})}{\pi_{\theta}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t})} \nabla_{\theta'} \log \pi_{\theta'}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \hat{Q}_{i,t} \quad (4.24)$$

## 4.5 REINFORCE Algorithm

- 1. Sample  $\{\tau_i\}$  from  $\pi_{\theta}(\mathbf{a}_t | \mathbf{s}_t)$  policy
- 2.  $\nabla_{\theta} J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \nabla_{\theta} \log \pi_{\theta}(\tau) \left( \sum_{t'=t}^T r(\mathbf{s}_{i,t'}, \mathbf{a}_{i,t'}) \right)$
- 3.  $\theta \leftarrow \theta + \alpha \nabla_{\theta} J(\theta)$  [Wil92]

When coding, use the pseudo loss as a weighted maximum likelihood:

$$\tilde{J}(\theta) \approx \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \log \pi_{\theta}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \hat{Q}_{i,t} \quad (4.25)$$

**Pseudo code:** (tensorflow)

```

1 logits = policy.predictions(states)
2 negative_likelihoods = tf.nn.softmax_cross_entropy(labels = actions, logits)
3 weighted_negative_likelihoods = tf.multiply(negative_likelihoods, q_values)
4 loss = tf.reduce_mean(weighted_negative_likelihoods)
5 gradients = loss.gradients(loss, variables)

```

with `q_values` already taking causality and baselines into account.

## 4.6 Natural Policy Gradient

Natural Policy gradients, [a.k.a.](#), covariant policy gradient, apply a trick to change the learning rate for different parameters. The high-level idea is such that some `params` change `prob.` a lot more than others. In other words, the vanilla policy gradient apply a constraint on the `params` space rather than the policy space. But with every gradient step, we rather want a constant

step in the policy space. [Kak01; PS08]

$$\max_{\Delta\theta} J(\theta + \Delta\theta) \approx J(\theta) + \Delta\theta^T \nabla_\theta J \quad (4.26)$$

$$\theta' \leftarrow \arg \max_{\theta'} (\theta' - \theta)^T \nabla_\theta J(\theta), \quad \|\theta' - \theta\|^2 \leq \epsilon \quad (\text{params. space}) \quad (4.27)$$

$$\theta' \leftarrow \arg \max_{\theta'} (\theta' - \theta)^T \nabla_\theta J(\theta), \quad D(\pi_{\theta'}, \pi_\theta) \leq \epsilon \quad (\text{policy space}) \quad (4.28)$$

A good choice for  $D(\pi_{\theta'}, \pi_\theta)$  is the Kullback–Leibler (KL)-divergence. To simplify the process, the KL-divergence is approximated with Fisher information matrix  $\mathbf{F}$  [Ama98]

$$D_{KL}(\pi_{\theta'} || \pi_\theta) \approx \frac{1}{2} (\theta' - \theta)^T \mathbf{F} (\theta' - \theta) = \frac{1}{2} \Delta\theta^T \mathbf{F} \Delta\theta \quad (4.29)$$

$$\mathbf{F} = \mathbb{E}_{\pi_\theta} [\nabla_\theta \log \pi_\theta(\mathbf{a}|\mathbf{s}) \nabla_\theta \log \pi_\theta(\mathbf{a}|\mathbf{s})^T] \quad (4.30)$$

$$\theta' \leftarrow \arg \max_{\theta'} (\theta' - \theta)^T \nabla_\theta J(\theta) \quad \text{s.t. } \|\theta' - \theta\|_{\mathbf{F}}^2 \leq \epsilon \quad (4.31)$$

$$\theta \leftarrow \theta + \alpha_n \mathbf{F}^{-1} \nabla_\theta J(\theta) \quad (4.32)$$

$$\alpha_n = \left[ \epsilon \left( \nabla J(\theta)^T \mathbf{F}_\theta^{-1} \nabla J(\theta) \right)^{-1} \right]^{\frac{1}{2}} \quad (4.33)$$

- Convergence to local minimum is guaranteed
- Faster convergence and avoids premature convergence of vanilla gradients
- Requires fewer data points for a good gradient estimate than vanilla gradients

# 5 Actor-Critic

Actor-Critic is kind of hybrid between policy gradient and value function based approach. Compared to deep Policy gradient, deep Actor-Critic has an extra network to learn the value function (the green box in Fig. 1.1).

- **the Actor is the policy**
- **the Critic is the value function (a.k.a. policy evaluation)**

## 5.1 Approach

We continue with the Eq. 4.16, where we multiply with the estimate of the expected reward  $\hat{Q}_{i,t}$ . The estimate  $\hat{Q}_{i,t}$  is currently calculated as the approximation of the sum of the reward afterward, from roll-outs. There are different ways we could go better than that single-sample estimate.

- $Q^\pi(\mathbf{s}_t, \mathbf{a}_t)$ : the Q-function, **a.k.a.**, the state-action value function, represents the total reward from taking  $\mathbf{a}_t$  at state  $\mathbf{s}_t$ , the *true expected* reward-to-go.

$$Q^\pi(\mathbf{s}_t, \mathbf{a}_t) = \sum_{t'=t}^T \mathbb{E}_{\pi_\theta}[r(\mathbf{s}_{t'}, a_{t'}) | \mathbf{s}_t, \mathbf{a}_t] \quad (5.1)$$

- $V^\pi(\mathbf{s}_t)$ : the state value function represents the total reward from state  $\mathbf{s}_t$ .

$$V^\pi(\mathbf{s}_t) = \mathbb{E}_{\mathbf{a}_t \sim \pi_\theta(\mathbf{a}_t, \mathbf{s}_t)}[Q^\pi(\mathbf{s}_t, \mathbf{a}_t)] \quad (5.2)$$

- $A^\pi(\mathbf{s}_t, \mathbf{a}_t)$ : the advantage function: represents how much action  $\mathbf{a}_t$  is better than average

$$A^\pi(\mathbf{s}_t, \mathbf{a}_t) = Q^\pi(\mathbf{s}_t, \mathbf{a}_t) - V^\pi(\mathbf{s}_t) \quad (5.3)$$

Using these value functions, we would have a better estimate for the policy gradients. Thus, we can rewrite the gradient as:

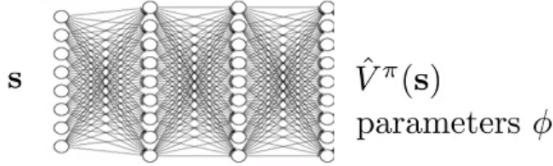

$$\nabla_\theta J(\theta) = \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_\theta \log \pi_\theta(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) A^\pi(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) \quad (5.4)$$

$$Q^\pi(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \mathbb{E}_{\mathbf{s}_{t+1} \sim p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t)} V^\pi(\mathbf{s}_{t+1}) \quad (\text{Eq. 5.1}) \quad (5.5)$$

$$\approx r(\mathbf{s}_t, \mathbf{a}_t) + V^\pi(\mathbf{s}_{t+1}) \quad (\text{with 1 sample}) \quad (5.6)$$

$$\Rightarrow A^\pi(\mathbf{s}_t, \mathbf{a}_t) \approx r(\mathbf{s}_t, \mathbf{a}_t) + V^\pi(\mathbf{s}_{t+1}) - V^\pi(\mathbf{s}_t) \quad (\text{Eq. 5.3}) \quad (5.7)$$

From the above derivation, let just fit the value function  $V^\pi(\mathbf{s})$  with a neural network. There are two possible approaches:

**Figure 5.1:** The network for value function  $V_\phi^\pi(s)$  with params.  $\phi$ .

- **Monte-Carlo:** just as with policy gradient, we approximate by the result from a single sample roll-out.

$$V^\pi(\mathbf{s}_t) \approx \sum_{t'=t}^T r(\mathbf{s}_{t'}, \mathbf{a}_{t'}) \quad (5.8)$$

The average of multiple samples would be a better approximation for the true expectation. However, we could not simply stop at one state within the trajectories and try out different actions. Single sample estimation is still pretty good!

$$\text{Better (but not possible)} \quad V^\pi(\mathbf{s}_t) \approx \frac{1}{N} \sum_{i=1}^N \sum_{t'=t}^T r(\mathbf{s}_{t'}, \mathbf{a}_{t'}) \quad (5.9)$$

$$\text{Training data: } \{(\mathbf{s}_{i,t}, y_{i,t})\} = \left\{ \left( \mathbf{s}_{i,t}, \sum_{t'=t}^T r(\mathbf{s}_{i,t'}, \mathbf{a}_{i,t'}) \right) \right\} \quad (5.10)$$

$$\text{Supervised regression: } \mathcal{L}(\phi) = \frac{1}{2} \sum_i \left\| \hat{V}_\phi^\pi(\mathbf{s}_i) - y_i \right\|^2 \quad (5.11)$$

- **Bootstrapped estimate:** use the previous fitted value function

$$y_{i,t} = \sum_{t'=t}^T \mathbb{E}_{\pi_\theta}[r(\mathbf{s}_{t'}, a_{t'} | \mathbf{s}_{i,t})] \quad \text{ideal target} \quad (5.12)$$

$$\approx r(\mathbf{s}_{i,t}, a_{i,t}) + V^\pi(\mathbf{s}_{i,t+1}) \quad (5.13)$$

$$\approx r(\mathbf{s}_{i,t}, a_{i,t}) + \hat{V}_\phi^\pi(\mathbf{s}_{i,t+1}) \quad (5.14)$$

$$\text{Training data: } \{(\mathbf{s}_{i,t}, y_{i,t})\} = \left\{ \left( \mathbf{s}_{i,t}, r(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) + \hat{V}_\phi^\pi(\mathbf{s}_{i,t+1}) \right) \right\} \quad (5.15)$$

$$\text{Supervised regression: } \mathcal{L}(\phi) = \frac{1}{2} \sum_i \left\| \hat{V}_\phi^\pi(\mathbf{s}_i) - y_i \right\|^2 \quad (5.16)$$

## 5.2 Batch Actor-Critic

- 1. Sample  $\{\mathbf{s}_i, \mathbf{a}_i\}$  from  $\pi_\theta(\mathbf{a}|\mathbf{s})$
2. Fit  $V_\phi^\pi(\mathbf{s})$  to sampled reward sums (either Monte-Carlo [SML+15] or bootstrapped estimate)
3. Evaluate  $\hat{A}^\pi(\mathbf{s}_i, \mathbf{a}_i) = r(\mathbf{s}_i, \mathbf{a}_i) + \hat{V}_\phi^\pi(\mathbf{s}_{i'}) - \hat{V}_\phi^\pi(\mathbf{s}_i)$
4.  $\nabla_\theta J(\theta) \approx \sum \nabla_\theta \log \pi_\theta(\mathbf{a}_i | \mathbf{s}_i) \hat{A}^\pi(\mathbf{a}_i, \mathbf{s}_i)$
5.  $\theta \leftarrow \theta + \alpha \nabla_\theta J(\theta)$

With **discount factor**  $\gamma \in [0, 1]$  (0.99 works well)

$$3. \text{ Evaluate } \hat{A}^\pi(\mathbf{s}_i, \mathbf{a}_i) = r(\mathbf{s}_i, \mathbf{a}_i) + \gamma \hat{V}_\phi^\pi(\mathbf{s}_{i'}) - \hat{V}_\phi^\pi(\mathbf{s}_i) \quad [\text{Tho14}]$$

### 5.3 Online Actor-Critic

- 1. Take action  $\mathbf{a} \sim \pi_\theta(\mathbf{a}|\mathbf{s})$ , get sample  $(\mathbf{s}, \mathbf{a}, \mathbf{s}', r)$
- 2. Update  $\hat{V}_\phi^\pi$  using target value  $r + \gamma \hat{V}_\phi^\pi(\mathbf{s}')$
- 3. Evaluate  $\hat{A}^\pi(\mathbf{s}, \mathbf{a}) = r(\mathbf{s}, \mathbf{a}) + \hat{V}_\phi^\pi(\mathbf{s}') - \hat{V}_\phi^\pi(\mathbf{s})$
- 4.  $\nabla_\theta J(\theta) \approx \nabla_\theta \log \pi_\theta(\mathbf{a}|\mathbf{s}) \hat{A}^\pi(\mathbf{s}, \mathbf{a})$
- 5.  $\theta \leftarrow \theta + \alpha \nabla_\theta J(\theta)$

**Problem:** single batch  $\Rightarrow$  need parallel actor-critic (synchronous / asynchronous) [MBM+16]

### 5.4 Design Decisions

- Architecture design:

Two separate networks	Shared network design
<p>+simple and stable -no shared features between actor &amp; critic</p>	<p>+could be more efficient in practice -two different gradients which need to be tuned</p>

- Critic as state-dependent baselines

Actor-critic:  
 +lower variance (due to critic)  
 -not unbiased (if the critic is not perfect)

$$\nabla_\theta J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_\theta \log \pi_\theta(\mathbf{a}_{i,t}|\mathbf{s}_{i,t}) (r(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) + \gamma \hat{V}_\phi^\pi(\mathbf{s}_{i,t+1}) - \hat{V}_\phi^\pi(\mathbf{s}_{i,t}))$$

Policy gradient:  
 +no bias  
 -higher variance (because of single-sample estimate)

$$\nabla_\theta J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_\theta \log \pi_\theta(\mathbf{a}_{i,t}|\mathbf{s}_{i,t}) \left( \left( \sum_{t'=t}^T \gamma^{t'-t} r(\mathbf{s}_{i,t'}, \mathbf{a}_{i,t'}) \right) - b \right)$$

$\Rightarrow$  Critic as baseline:  
 +no bias  
 +lower variance (baseline is closer to rewards)

$$\nabla_\theta J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_\theta \log \pi_\theta(\mathbf{a}_{i,t}|\mathbf{s}_{i,t}) \left( \left( \sum_{t'=t}^T \gamma^{t'-t} r(\mathbf{s}_{i,t'}, \mathbf{a}_{i,t'}) \right) - \hat{V}_\phi^\pi(\mathbf{s}_{i,t}) \right)$$

This doesn't lower the variance as much as in the actor-critic algorithm. But it is much lower than using a constant baseline, and it's still unbiased.

- Control variates: action-dependent baselines [GLG+16]

We could go further with a state dependent baseline, and have a action-and-state-dependent baselines. The variance is now even lower, but it's getting much more complicated.

$\hat{A}^\pi(\mathbf{s}_t, \mathbf{a}_t) = \sum_{t'=t}^{\infty} \gamma^{t'-t} r(\mathbf{s}_{t'}, \mathbf{a}_{t'}) - V_\phi^\pi(\mathbf{s}_t)$	+no bias (state dependent baseline) -still high variance (compared to actor-critic)
$\hat{A}^\pi(\mathbf{s}_t, \mathbf{a}_t) = \sum_{t'=t}^{\infty} \gamma^{t'-t} r(\mathbf{s}_{t'}, \mathbf{a}_{t'}) - Q_\phi^\pi(\mathbf{s}_t, \mathbf{a}_t)$	+goes to 0 in expectation if critic is correct -not correct

The second one lead to wrong policy gradient, thus must be corrected with an error term:

$$\nabla_{\theta} J(\theta) \approx \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_{\theta} \log \pi_{\theta}(\mathbf{a}_{i,t} | \mathbf{s}_{i,t}) \left( \hat{Q}_{i,t} - Q_{\phi}^{\pi}(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) \right) + \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_{\theta} \mathbb{E}_{\mathbf{a} \sim \pi_{\theta}(\mathbf{a}_t | \mathbf{s}_{i,t})} [Q_{\phi}^{\pi}(\mathbf{s}_{i,t}, \mathbf{a}_{i,t})] \quad (5.17)$$

- Eligibility traces &  $n$ -step returns: reduces the bias [MBM+16]

$$\text{Actor-critic: } \hat{A}_C^\pi(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \gamma \hat{V}_\phi^\pi(\mathbf{s}_{t+1}) - \hat{V}_\phi^\pi(\mathbf{s}_t) \quad \begin{matrix} \text{+low variance} \\ \text{-but biased} \end{matrix} \quad (5.18)$$

$$\text{Monte-Carlo: } \hat{A}_{MC}^{\pi}(\mathbf{s}_t, \mathbf{a}_t) = \sum_{t'=t}^{\infty} \gamma^{t'-t} r(\mathbf{s}_{t'}, a_{t'}) - \hat{V}_{\phi}^{\pi}(\mathbf{s}_t) \quad \begin{array}{l} \text{+no bias} \\ \text{-higher variance} \end{array} \quad (5.19)$$

$$\Rightarrow \hat{A}_n^\pi(\mathbf{s}_t, \mathbf{a}_t) = \sum_{\substack{t'=t \\ t'=t}}^{t+n} \gamma^{t'-t} r(\mathbf{s}_{t'}, a_{t'}) - \hat{V}_\phi^\pi(\mathbf{s}_t) + \gamma^n \hat{V}_\phi^\pi(\mathbf{s}_{t+n}) \quad (5.20)$$

Simply put, the further the states are in the future, the higher the variance of those states. E.g., where would you/the robot be in 5 minutes versus where would you/the robot be in 20 years? The larger  $n$  is, the lower the bias, the higher the variance.

- Generalized advantage estimation: extension of  $n$ -step returns [SML+15]

To have many  $n$ -step returns, then take weighted average of them.

$$\widehat{A}_{GAE}^{\pi}(\mathbf{s}_t, \mathbf{a}_t) = \sum_{n=1}^{\infty} \omega_n \widehat{A}_n^{\pi}(\mathbf{s}_t, \mathbf{a}_t), \quad \omega_n \propto \lambda^{n-1} \quad (5.21)$$

$$\Rightarrow \widehat{A}_{GAE}^{\pi}(\mathbf{s}_t, \mathbf{a}_t) = \sum_{t'=t}^{\infty} (\gamma \lambda)^{t'-t} \delta_{t'}, \quad \delta_{t'} = r(\mathbf{s}_{t'}, \mathbf{a}_{t'}) + \gamma \widehat{V}_{\phi}^{\pi}(\mathbf{s}_{t'+1}) - \widehat{V}_{\phi}^{\pi}(\mathbf{s}_{t'}) \quad (5.22)$$

## 5.5 Natural Actor-Critic

Natural Actor-Critic [PVS05] is the extension of natural policy gradient [Kak01] to actor-critic approach. [PS08]

## 5.6 Off-policy Actor-Critic

SAC algorithm: [HZA+18]

- 1. Take action  $\mathbf{a} \sim \pi_\theta(\mathbf{a}|\mathbf{s})$ , get  $(\mathbf{s}, \mathbf{a}, \mathbf{s}', r)$ , store in buffer  $\mathcal{B}$
- 2. Sample a batch  $(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)$  from  $\mathcal{B}$
- 3. Update  $\hat{Q}_\phi^\pi$  using targets  $y_i = r_i + \gamma \hat{Q}_\phi^\pi(\mathbf{s}'_i, \mathbf{a}'_i)$ ,  $\mathbf{a}'_i \sim \pi_\theta(\mathbf{a}'_i|\mathbf{s}'_i)$
- 4.  $\nabla_\theta J(\theta) \approx \frac{1}{N} \sum_i \nabla_\theta \log \pi_\theta(\mathbf{a}_i^\pi|\mathbf{s}_i) \hat{Q}^\pi(\mathbf{s}_i, \mathbf{a}_i^\pi)$ ,  $\mathbf{a}_i^\pi \sim \pi_\theta(\mathbf{a}|\mathbf{s}_i)$
- 5.  $\theta \leftarrow \theta + \alpha \nabla_\theta J(\theta)$

**NOTE:** In step 3 and 4, the actions are not from the replay buffer  $\mathcal{B}$ , but from our current policy  $\mathbf{a}'_i \sim \pi_\theta(\mathbf{a}'_i|\mathbf{s}'_i)$  and  $\mathbf{a}_i^\pi \sim \pi_\theta(\mathbf{a}|\mathbf{s}_i)$

# 6 Value Function Based Algorithms

## 6.1 Approach

Knowing the value functions, we could just remove the policy gradient completely. The advantage function  $A^\pi(\mathbf{s}_t, \mathbf{a}_t)$  tells how much better is  $\mathbf{a}_t$  than the average action according to policy  $\pi$ , regardless of what  $\pi(\mathbf{a}_t|\mathbf{s}_t)$  is. We could have a policy  $\pi'$  by simply choosing the current best action.  $\pi'$  would be as good as  $\pi$  (probably better).

### High-level idea for Policy Iteration:

- 1. Evaluate  $A^\pi(s, a)$  (policy evaluation)
- 2. Set  $\pi \leftarrow \pi'$

$$\pi'(\mathbf{a}_t|\mathbf{s}_t) = \begin{cases} 1 & \text{if } \mathbf{a}_t = \arg \max_{\mathbf{a}_t} A^\pi(\mathbf{s}_t, \mathbf{a}_t) \\ 0 & \text{otherwise} \end{cases} \quad (6.1)$$

## 6.2 Policy Iteration with Dynamic Programming

### Dynamic Programming:

- Assume we know  $p(\mathbf{s}'|\mathbf{s}, \mathbf{a})$
- $\mathbf{s}$  and  $\mathbf{a}$  are both discrete and small
- $V^\pi(\mathbf{s})$  can be stored in a lookup table
- $\mathcal{T}$  is a tensor

### Algorithm:

- 1.  $V^\pi(\mathbf{s}) \leftarrow r(\mathbf{s}, \pi(\mathbf{s})) + \gamma \mathbb{E}_{\mathbf{s}' \sim p(\mathbf{s}'|\mathbf{s}, \pi(\mathbf{s}))}[V^\pi(\mathbf{s}')]$
- 2. Set  $\pi \leftarrow \pi'$

## 6.3 Value Iteration Algorithm

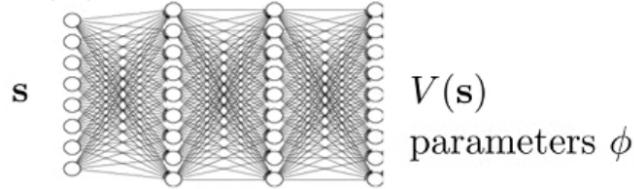

Since  $\arg \max_{\mathbf{a}_t'} A^\pi(\mathbf{s}_t, \mathbf{a}_t) = \arg \max_{\mathbf{a}_t'} Q^\pi(\mathbf{s}_t, \mathbf{a}_t)$ , we can simplify above algor.:

- 1. Set  $Q^\pi(\mathbf{s}, \mathbf{a}) \leftarrow r(\mathbf{s}, \mathbf{a}) + \gamma \mathbb{E}[V^\pi(\mathbf{s}')]$
- 2. Set  $V^\pi(\mathbf{s}) \leftarrow \max_{\mathbf{a}} Q^\pi(\mathbf{s}, \mathbf{a})$

## 6.4 Fitted Value Iteration

The above two approaches still have a table to fit the value functions. For larger state space (either continuous or discrete), when facing the curse of dimensionality (for  $s$ ), we shall use neural network to evaluate the value functions.

- 1.  $\mathbf{y}_i \leftarrow \max_{\mathbf{a}_i} r(\mathbf{s}_i, \mathbf{a}_i) + \gamma \mathbb{E}[V_\phi(\mathbf{s}'_i)]$
- 2.  $\phi \leftarrow \arg \min_{\phi} \frac{1}{2} \sum_i \|V_\phi(\mathbf{s}_i) - \mathbf{y}_i\|^2$

**Figure 6.1:** The network for value function  $V_\phi(s)$  with params.  $\phi$ .

**Problem:** still need to know transition dynamic.

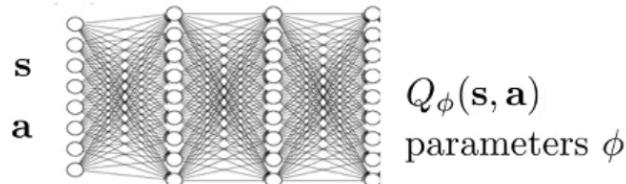

## 6.5 Fully fitted Q-Iteration

Policy evaluation:

- $V^\pi(\mathbf{s}) \leftarrow r(\mathbf{s}, \pi(\mathbf{s})) + \gamma \mathbb{E}_{\mathbf{s}' \sim p(\mathbf{s}'|\mathbf{s}, \pi(\mathbf{s}))}[V^\pi(\mathbf{s}')]$  needs to know the transition models
- $Q^\pi(\mathbf{s}, \mathbf{a}) \leftarrow r(\mathbf{s}, \mathbf{a}) + \gamma \mathbb{E}_{\mathbf{s}' \sim p(\mathbf{s}'|\mathbf{s}, \mathbf{a})}[Q^\pi(\mathbf{s}', \pi(\mathbf{s}'))]$  needs only a sample tuple  $\{\mathbf{s}, \mathbf{a}, \mathbf{s}'\}$

Replacing since  $\mathbb{E}[V(\mathbf{s}'_i)] \approx \max_{\mathbf{a}'} Q_\phi(\mathbf{s}'_i, \mathbf{a}'_i)$  into fitted value iteration algorithm, we have Fully fitted Q-iteration:

- 1. Collect dataset:  $\{(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)\}$  using some policy
- 2. Set  $\mathbf{y}_i \leftarrow r(\mathbf{s}_i, \mathbf{a}_i) + \gamma \max_{\mathbf{a}'_i} Q_\phi(\mathbf{s}'_i, \mathbf{a}'_i)$
- 3. Set  $\phi \leftarrow \arg \min_{\phi} \frac{1}{2} \sum_i \|Q_\phi(\mathbf{s}_i, \mathbf{a}_i) - \mathbf{y}_i\|^2$

**Figure 6.2:** The network for Q-value function  $Q_\phi(s, a)$  with params.  $\phi$ .

+Off-policy (unlike actor-critic)

+Single network, no high-variance policy gradient

-Not really converge

## 6.6 Online Q-Iteration Algorithm

- 1. Take some action  $\mathbf{a}_i$  and observe  $(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)$       **1 sample off policy**  
 2.  $\mathbf{y}_i \leftarrow r(\mathbf{s}_i, \mathbf{a}_i) + \gamma \max_{\mathbf{a}'_i} Q_\phi(\mathbf{s}'_i, \mathbf{a}'_i)$   
 3.  $\phi \leftarrow \phi - \alpha \frac{dQ_\phi}{d\phi}(\mathbf{s}_i, \mathbf{a}_i) [Q_\phi(\mathbf{s}_i, \mathbf{a}_i) - \mathbf{y}_i]$       **1 gradient step**

### Problems:

- Sequential states are strongly correlated ⇒ Replay buffer
- Target value is always changing ⇒ Target network

## 6.7 Exploration vs Exploitation

- Epsilon greedy

$$\pi(\mathbf{a}_t | \mathbf{s}_t) = \begin{cases} 1 - \epsilon & \text{if } \mathbf{a}_t = \arg \max_{\mathbf{a}_t} A^\pi(\mathbf{s}_t, \mathbf{a}_t) \\ \frac{\epsilon}{|\mathcal{A}| - 1} & \text{otherwise} \end{cases} \quad (6.2)$$

- Boltzmann exploration (**very large or continuous action-space**)

$$\pi(\mathbf{a}_t | \mathbf{s}_t) \propto \exp(Q_\phi(\mathbf{s}_t, \mathbf{a}_t)) \quad (6.3)$$

## 6.8 Q-learning

Q-learning with replay buffer  $\mathcal{B}$  and target network  $\phi'$ :

- 1. Save target network **params.**  $\phi' \leftarrow \phi$   
 → 2. Collect dataset  $\{(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)\}$  using some policy, add it to  $\mathcal{B}$   
 $N \times K \times$   
 → 3. Sample a batch  $(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)$  from  $\mathcal{B}$   
 → 4.  $\phi \leftarrow \phi - \alpha \sum_i \frac{dQ_\phi}{d\phi}(\mathbf{s}_i, \mathbf{a}_i) \left( Q_\phi(\mathbf{s}_i, \mathbf{a}_i) - \left[ r(\mathbf{s}_i, \mathbf{a}_i) + \gamma \max_{\mathbf{a}'_i} Q_{\phi'}(\mathbf{s}'_i, \mathbf{a}'_i) \right] \right)$   
 $K \in [1, 4], N \approx 10,000$

## 6.9 Deep Q-learning

- 1. Take some action  $\mathbf{a}_i$  and observe  $(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)$ , add it to  $\mathcal{B}$   
 2. Sample mini-batch  $\{(\mathbf{s}_j, \mathbf{a}_j, \mathbf{s}'_j, r_j)\}$  from  $\mathcal{B}$  uniformly  
 3. Compute  $y_j = r_j + \gamma \max_{\mathbf{a}'_j} Q_{\phi'}(\mathbf{s}'_j, \mathbf{a}'_j)$  using *target network*  $Q_{\phi'}$   
 4.  $\phi \leftarrow \phi - \alpha \sum_j \frac{dQ_\phi}{d\phi}(\mathbf{s}_j, \mathbf{a}_j) (Q_\phi(\mathbf{s}_j, \mathbf{a}_j) - y_j)$   
 5. Update  $\phi'$ : copy  $\phi$  every  $N$  steps

## 6 Value Function Based Algorithms

The above "Classic" DQN is essentially Q-learning with  $K = 1$  [MKS+15]

Improving DQN:

- Alternative: Step 5. Update  $\phi' \leftarrow \tau\phi' + (1 - \tau)\phi$ ,  $\tau = 0.999$  (Polyak averaging)
- Double Q-learning: **helps a lot, solve over-estimate problem, no downside**  
⇒ **should always use**

$$\text{Standard Q-learning: } y = r + \gamma Q_{\phi'} \left( s', \arg \max_{a'} Q_{\phi'}(s', a') \right) \quad (6.4)$$

$$\text{Double Q-learning: } y = r + \gamma Q_{\phi'} \left( s', \arg \max_{a'} Q_{\phi'}(s', a') \right) \quad (6.5)$$

- Multi-Step returns: **helps a lot, have DOWNSIDE ⇒ frequently use** [MSH+16]

$$\text{Q-learning target: } y_{i,t} = r_{i,t} + \gamma \max_{a_{i,t+1}} Q_{\phi'}(\mathbf{s}_{i,t+1}, a_{i,t+1}) \quad (6.6)$$

$$\text{Multi-step target: } y_{i,t} = \sum_{t'=t}^{t+N-1} \gamma^{t'-t} r_{i,t'} + \gamma^N \max_{a_{i,t+N}} Q_{\phi'}(\mathbf{s}_{i,t+N}, a_{i,t+N}) \quad (6.7)$$

+less biased target values when Q-values are inaccurate

+typically faster learning, especially early on

-Only actually CORRECT when learning on-policy

## 6.10 Q-learning with continuous action-space

[TODO: ]

## 6.11 Tips for Q-learning

- Large replay buffer helps improve stability (1 Million).
- Apply Prioritized Experience Replay [SQA+15]
- It takes time, be patient - might be no better than random for a while
- Start with high exploration ⇒ gradually reduce
- Bellman error gradient can be quite large ⇒ clip gradients / use Huber loss

$$L(x) = \begin{cases} \frac{x^2}{2} & \text{if } |x| \leq \delta \\ \delta|x| - \frac{\delta^2}{2} & \text{otherwise} \end{cases} \quad (\text{Huber loss}) \quad (6.8)$$

- Run multiple random seeds, it's very **inconsistent** between runs.

## 6.12 Policy Gradient as Policy Iteration

[TODO: math stuffs]

# 7 Optimal Control

Prior approaches are all model-free algorithms. They either assume the dynamics model is unknown or don't even attempt to learn it. On the other hands, there are times that we either do know the dynamics transition or can learn it. **Knowing the dynamics model actually does make thing easier.** These section is about what we do, how to plan through the action sequence to maximize the reward, **IF we already know the model.**

- Deterministic case vs Stochastic:

$$\mathbf{a}_1, \dots, \mathbf{a}_T = \arg \max_{\mathbf{a}_1, \dots, \mathbf{a}_T} \sum_{t=1}^T r(\mathbf{s}_t, \mathbf{a}_t) \quad \text{s.t. } \mathbf{s}_{t+1} = f(\mathbf{s}_t, \mathbf{a}_t) \quad (\text{Deterministic case}) \quad (7.1)$$

$$\mathbf{a}_1, \dots, \mathbf{a}_T = \arg \max_{\mathbf{a}_1, \dots, \mathbf{a}_T} \mathbb{E} \left[ \sum_t r(\mathbf{s}_t, \mathbf{a}_t) | \mathbf{a}_1, \dots, \mathbf{a}_T \right] \quad (\text{Stochastic case}) \quad (7.2)$$

$$p_\theta(\mathbf{s}_1, \dots, \mathbf{s}_T | \mathbf{a}_1, \dots, \mathbf{a}_T) = p(\mathbf{s}_1) \prod_{t=1}^T p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \quad (\text{stochastic dynamics}) \quad (7.3)$$

- Open-loop case vs Closed-loop:

Open-loop case: we are only given  $\mathbf{s}_1$  and have to plan through the whole sequence of actions  $\mathbf{a}_1, \dots, \mathbf{a}_T$ . In deterministic case, it's still possible to come up with a good action plan. But for stochastic case, the randomness would probably drive us to a bad result.

Closed-loop case: we plan once action  $\mathbf{a}_t$  at a time and observe the state transition  $\mathbf{s}_{t+1}$

## 7.1 Open-Loop Planning

Maximize objective through sequence of actions:

$$\mathbf{a}_1, \dots, \mathbf{a}_T = \arg \max_{\mathbf{a}_1, \dots, \mathbf{a}_T} J(\mathbf{a}_1, \dots, \mathbf{a}_T) \quad \Rightarrow \quad \mathbf{A} = \arg \max_{\mathbf{A}} J(\mathbf{A}) \quad (7.4)$$

Some stochastic optimization:

- Guess and Check (**Random Shooting Method**)
  1. Pick  $\mathbf{A}_1, \dots, \mathbf{A}_N$  from some distribution (e.g., uniform)
  2. Choose  $\mathbf{A}_i$  based on  $\arg \max_i J(\mathbf{A}_i)$
- Cross-entropy Method (**CEM**)
 

1. Sample  $\mathbf{A}_1, \dots, \mathbf{A}_N$  from  $p(\mathbf{A})$
  2. Evaluate  $J(\mathbf{A}_1), \dots, J(\mathbf{A}_N)$
  3. Pick  $M$  elites  $\mathbf{A}_{i_1}, \dots, \mathbf{A}_{i_M}$  with highest values  $M < N$  (usually 10%)
  4. Refit  $p(\mathbf{A})$  to the elites  $\mathbf{A}_{i_1}, \dots, \mathbf{A}_{i_M}$

**NOTE:** Check out CMA-ES ([CEM](#) with momentum)

The two above approaches are:

- +very fast if parallelized
- +extremely simple
- very harsh dimensionality limit
- only open-loop planning

- Discrete case: Monte-Carlo Tree Search ([MCTS](#)) [[BPW+12](#)]

- 1. Find a leaf  $s_l$  using  $\text{TreePolicy}(s_1)$
- 2. Evaluate the leaf using  $\text{DefaultPolicy}(s_l)$
- 3. Update all values in tree between  $s_1$  and  $s_l$ , take the best action from  $s_1$ .

UCT Tree Policy( $s_t$ ): if  $s_t$  is not fully expanded, choose new  $a_t$ , else choose child with the highest Score( $s_{t+1}$ )

$$\text{Score}(s_t) = \frac{Q(s_t)}{N(s_t)} + 2C \sqrt{\frac{2 \ln N(s_{t-1})}{N(s_t)}}$$

With  $Q(s_t)$  as the reward,  $N(s_t)$  as the [no.](#) times the leaf is visited.

## 7.2 Trajectory Optimization with Derivatives

Derivatives are hard to come by, but SOMETIMES you **CAN**, through Physics equation.

$$\min_{\mathbf{u}_1, \dots, \mathbf{u}_T} \sum_{t=1}^T c(\mathbf{x}_t, \mathbf{u}_t) \quad \text{s.t. } \mathbf{x}_t = f(\mathbf{x}_{t-1}, \mathbf{u}_{t-1}) \quad (7.5)$$

$$= \min_{\mathbf{u}_1, \dots, \mathbf{u}_T} c(\mathbf{x}_1, \mathbf{u}_1) + c(f(\mathbf{x}_1, \mathbf{u}_1), \mathbf{u}_2) + \dots + c(f(f(\dots)), \mathbf{u}_T) \quad (7.6)$$

**NOTE:** Shooting methods [vs.](#) collocation:

- Shooting methods: optimize over actions only

$$\min_{\mathbf{u}_1, \dots, \mathbf{u}_T} c(\mathbf{x}_1, \mathbf{u}_1) + c(f(\mathbf{x}_1, \mathbf{u}_1), \mathbf{u}_2) + \dots + c(f(f(\dots)), \mathbf{u}_T)$$

tends to be very sensitive with early actions and leads to numerical instability.

- Collocation: optimize over actions and states, with constraints

$$\min_{\mathbf{u}_1, \dots, \mathbf{u}_T, \mathbf{x}_1, \dots, \mathbf{x}_T} \sum_{t=1}^T c(\mathbf{x}_t, \mathbf{u}_t) \quad \text{s.t. } \mathbf{x}_t = f(\mathbf{x}_{t-1}, \mathbf{u}_{t-1})$$

**Linear case: Linear Quadratic Regulator (LQR):**  $f(\cdot)$  has special structure.

$$f(\mathbf{x}_t, \mathbf{u}_t) = \mathbf{F}_t \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix} + \mathbf{f}_t \quad \text{linear dynamics} \quad (7.7)$$

$$c(\mathbf{x}_t, \mathbf{u}_t) = \frac{1}{2} \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix}^T \mathbf{C}_t \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix} + \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix}^T \mathbf{c}_t \quad \text{quadratic cost} \quad (7.8)$$

$$\mathbf{C}_T = \begin{bmatrix} \mathbf{C}_{\mathbf{x}_T, \mathbf{x}_T} & \mathbf{C}_{\mathbf{x}_T, \mathbf{u}_T} \\ \mathbf{C}_{\mathbf{u}_T, \mathbf{x}_T} & \mathbf{C}_{\mathbf{u}_T, \mathbf{u}_T} \end{bmatrix}; \quad \mathbf{c}_T = \begin{bmatrix} c_{\mathbf{x}_T} \\ c_{\mathbf{u}_T} \end{bmatrix} \quad (7.9)$$

**NOTE:** LQR and its extensions are also an open-loop plannings.

Solve for  $\mathbf{u}_T$  only:

$$Q(\mathbf{x}_T, \mathbf{u}_T) = \text{const} + \frac{1}{2} \begin{bmatrix} \mathbf{x}_T \\ \mathbf{u}_T \end{bmatrix}^T \mathbf{C}_T \begin{bmatrix} \mathbf{x}_T \\ \mathbf{u}_T \end{bmatrix} + \begin{bmatrix} \mathbf{x}_T \\ \mathbf{u}_T \end{bmatrix}^T \mathbf{c}_T \quad (7.10)$$

$$\text{Set } \nabla_{\mathbf{u}_T} Q(\mathbf{x}_T, \mathbf{u}_T) = \mathbf{C}_{\mathbf{u}_T, \mathbf{x}_T} \mathbf{x}_T + \mathbf{C}_{\mathbf{u}_T, \mathbf{u}_T} \mathbf{u}_T + \mathbf{c}_{\mathbf{u}_T}^T = 0 \quad (7.11)$$

$$\Rightarrow \mathbf{u}_T = -\mathbf{C}_{\mathbf{u}_T, \mathbf{u}_T}^{-1} (\mathbf{C}_{\mathbf{u}_T, \mathbf{x}_T} \mathbf{x}_T + \mathbf{c}_{\mathbf{u}_T}) = \mathbf{K}_T \mathbf{x}_T + \mathbf{k}_T \quad (7.12)$$

$$\mathbf{K}_T = -\mathbf{C}_{\mathbf{u}_T, \mathbf{u}_T}^{-1} \mathbf{C}_{\mathbf{u}_T, \mathbf{x}_T} \quad (7.13)$$

$$\mathbf{k}_T = -\mathbf{C}_{\mathbf{u}_T, \mathbf{u}_T}^{-1} \mathbf{c}_{\mathbf{u}_T} \quad (7.14)$$

$$(7.15)$$

Replace Eq. 7.12 into Eq. 7.10:

$$\Rightarrow V(\mathbf{x}_T) = \text{const} + \frac{1}{2} \begin{bmatrix} \mathbf{x}_T \\ \mathbf{K}_T \mathbf{x}_T + \mathbf{k}_T \end{bmatrix}^T \mathbf{C}_T \begin{bmatrix} \mathbf{x}_T \\ \mathbf{K}_T \mathbf{x}_T + \mathbf{k}_T \end{bmatrix} + \begin{bmatrix} \mathbf{x}_T \\ \mathbf{K}_T \mathbf{x}_T + \mathbf{k}_T \end{bmatrix}^T \mathbf{c}_T \quad (7.16)$$

$$= \text{const} + \frac{1}{2} \mathbf{x}_T^T \mathbf{V}_T \mathbf{x}_T + \mathbf{x}_T^T \mathbf{v}_T \quad (7.17)$$

**Minimize objective on last action  $u_T$ , based on  $x_T$**   
 **$u_{T-1}$  affects objectives through linear dynamics func. to  $x_T$**

Backward recursion:

$$\begin{aligned}
 &\rightarrow \text{for } t = T \rightarrow 1 : & (7.18) \\
 &\mathbf{Q}_t = \mathbf{C}_t + \mathbf{F}_t^T \mathbf{V}_{t+1} \mathbf{F}_t & (7.19) \\
 &\mathbf{q}_t = \mathbf{c}_t + \mathbf{F}_t^T \mathbf{V}_{t+1} \mathbf{f}_t + \mathbf{F}_t^T \mathbf{v}_{t+1} & (7.20) \\
 &Q(\mathbf{x}_t, \mathbf{u}_t) = \text{const} + \frac{1}{2} \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix}^T \mathbf{Q}_t \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix} + \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix}^T \mathbf{q}_t & (7.21) \\
 &\mathbf{u}_t \leftarrow \arg \min_{u_t} Q(\mathbf{x}_t, \mathbf{u}_t) = \mathbf{K}_t \mathbf{x}_t + \mathbf{k}_t & (7.22) \\
 &\mathbf{K}_t = -\mathbf{Q}_{\mathbf{u}_t, \mathbf{u}_t}^{-1} \mathbf{Q}_{\mathbf{u}_t, \mathbf{x}_t} & (7.23) \\
 &\mathbf{k}_t = -\mathbf{Q}_{\mathbf{u}_t, \mathbf{u}_t}^{-1} \mathbf{q}_{\mathbf{u}_t} & (7.24) \\
 &\mathbf{V}_t = \mathbf{Q}_{\mathbf{x}_t, \mathbf{x}_t} + \mathbf{Q}_{\mathbf{x}_t, \mathbf{u}_t} \mathbf{K}_t + \mathbf{K}_t^T \mathbf{Q}_{\mathbf{u}_t, \mathbf{x}_t} + \mathbf{K}_t^T \mathbf{Q}_{\mathbf{u}_t, \mathbf{u}_t} \mathbf{K}_t & (7.25) \\
 &\mathbf{v}_t = \mathbf{q}_{\mathbf{x}_t} + \mathbf{Q}_{\mathbf{x}_t, \mathbf{u}_t} \mathbf{k}_t + \mathbf{K}_t^T \mathbf{q}_{u_t} + \mathbf{K}_t^T \mathbf{Q}_{\mathbf{u}_t, \mathbf{u}_t} \mathbf{k}_t & (7.26) \\
 &\boxed{V(\mathbf{x}_t) = \text{const} + \frac{1}{2} \mathbf{x}_t^T \mathbf{V}_t \mathbf{x}_t + \mathbf{x}_t^T \mathbf{v}_t} & (7.27)
 \end{aligned}$$

Forward recursion:

$$\begin{aligned}
 &\rightarrow \text{for } t = 1 \rightarrow T : & (7.28) \\
 &\mathbf{u}_t = \mathbf{K}_t \mathbf{x}_t + \mathbf{k}_t & (7.29) \\
 &\boxed{\mathbf{x}_{t+1} = f(\mathbf{x}_t, \mathbf{u}_t)} & (7.30)
 \end{aligned}$$

### LQR for Stochastic and Non-Linear Systems

- Stochastic dynamics:

$$\mathbf{x}_{t+1} \sim p(\mathbf{x}_{t+1} | \mathbf{x}_t, \mathbf{u}_t) \quad (7.31)$$

$$p(\mathbf{x}_{t+1} | \mathbf{x}_t, \mathbf{u}_t) = \mathcal{N} \left( \mathbf{F}_t \begin{bmatrix} \mathbf{x}_t \\ \mathbf{u}_t \end{bmatrix} + \mathbf{f}_t, \Sigma_t \right) \quad (7.32)$$

Solution: choose actions according to  $\mathbf{u}_t = \mathbf{K}_t \mathbf{x}_t + \mathbf{k}_t$

- Non-linear case: Differential Dynamic Programming (DDP) or Iterative Linear Quadratic Regulator (iLQR)

At every iteration: we linearize local nonlinear dynamic (with Taylor expansion) as a linear-quadratic system

$$f(\mathbf{x}_t, \mathbf{u}_t) \approx f(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) + \nabla_{\mathbf{x}_t, \mathbf{u}_t} f(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \begin{bmatrix} \mathbf{x}_t - \hat{\mathbf{x}}_t \\ \mathbf{u}_t - \hat{\mathbf{u}}_t \end{bmatrix} \quad (7.33)$$

$$c(\mathbf{x}_t, \mathbf{u}_t) \approx c(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) + \nabla_{\mathbf{x}_t, \mathbf{u}_t} c(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \begin{bmatrix} \mathbf{x}_t - \hat{\mathbf{x}}_t \\ \mathbf{u}_t - \hat{\mathbf{u}}_t \end{bmatrix} + \frac{1}{2} \begin{bmatrix} \mathbf{x}_t - \hat{\mathbf{x}}_t \\ \mathbf{u}_t - \hat{\mathbf{u}}_t \end{bmatrix}^T \nabla_{\mathbf{x}_t, \mathbf{u}_t}^2 c(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \begin{bmatrix} \mathbf{x}_t - \hat{\mathbf{x}}_t \\ \mathbf{u}_t - \hat{\mathbf{u}}_t \end{bmatrix} \quad (7.34)$$

We can run LQR with dynamics  $\bar{f}$ , cost  $\bar{c}$ , state  $\delta \mathbf{x}_t$  and action  $\delta \mathbf{u}_t$ :

$$\delta \mathbf{x}_t = \mathbf{x}_t - \hat{\mathbf{x}}_t \quad (7.35)$$

$$\delta \mathbf{u}_t = \mathbf{u}_t - \hat{\mathbf{u}}_t \quad (7.36)$$

$$\bar{f}(\delta \mathbf{x}_t, \delta \mathbf{u}_t) = \mathbf{F}_t \begin{bmatrix} \delta \mathbf{x}_t \\ \delta \mathbf{u}_t \end{bmatrix} \quad \text{with } \mathbf{F}_t = \nabla_{\mathbf{x}_t, \mathbf{u}_t} f(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \quad (7.37)$$

$$\bar{c}(\delta \mathbf{x}_t, \delta \mathbf{u}_t) = \frac{1}{2} \begin{bmatrix} \delta \mathbf{x}_t \\ \delta \mathbf{u}_t \end{bmatrix}^T \mathbf{C}_t \begin{bmatrix} \delta \mathbf{x}_t \\ \delta \mathbf{u}_t \end{bmatrix} + \begin{bmatrix} \delta \mathbf{x}_t \\ \delta \mathbf{u}_t \end{bmatrix}^T \mathbf{c}_t \quad \text{with } \mathbf{C}_t = \nabla_{\mathbf{x}_t, \mathbf{u}_t}^2 c(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \quad (7.38)$$

$\Rightarrow$  iLQR (simplified pseudo code):

→ until convergence:

$$\mathbf{F}_t = \nabla_{\mathbf{x}_t, \mathbf{u}_t} f(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \quad (7.40)$$

$$\mathbf{C}_t = \nabla_{\mathbf{x}_t, \mathbf{u}_t}^2 c(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \quad (7.41)$$

$$\mathbf{c}_t = \nabla_{\mathbf{x}_t, \mathbf{u}_t} c(\hat{\mathbf{x}}_t, \hat{\mathbf{u}}_t) \quad (7.42)$$

Run LQR backward pass on state  $\delta \mathbf{x}_t$  and action  $\delta \mathbf{u}_t$

Run forward pass with  $\mathbf{u}_t = \mathbf{K}_t(\mathbf{x}_t - \hat{\mathbf{x}}_t) + \alpha \mathbf{k}_t + \hat{\mathbf{u}}_t$

Update  $\hat{\mathbf{x}}_t$  and  $\hat{\mathbf{u}}_t$  based on states and actions in forward pass

**NOTE:** For practical improvement, use  $\alpha \in [0, 1]$ . When running the forward pass, we should run over different  $\alpha$  until we find something good.

# 8 Model-based RL

For many current complex situation, it's too optimistic to assume that we will know the precise model e.g., with the task of folding clothes. This section aims to learn the model.

## 8.1 Model-based RL v.0.5

1. Run based policy  $\pi_0(\mathbf{a}_t|\mathbf{s}_t)$  (e.g., random policy) to collect  $\mathcal{D} = \{(\mathbf{s}, \mathbf{a}, \mathbf{s}')_i\}$
2. Learn dynamic model  $f(\mathbf{s}, \mathbf{a})$  to minimize  $\sum_i \|f(\mathbf{s}_i, \mathbf{a}_i) - \mathbf{s}'_i\|^2$
3. Plan through  $f(\mathbf{s}, \mathbf{a})$  to choose actions

**Problems:** might go beyond to new state distribution  $p_{\pi_f}(\mathbf{s}_t) \neq p_{\pi_0}(\mathbf{s}_t)$ .

- If the states are discrete, we could use cross-entropy loss. If the states are continuous, we could use squared-error loss. Generally, negative log-likelihood loss.
- Good based policy should be taken with good care.
- Particularly effective *if* can hand-engineer a dynamics representation with our knowledge of physics ...  $\Rightarrow$  need to fit only a few **params**.

## 8.2 Model-based RL v.1.0

Similar solution for distribution mismatch as in Sec. ??.

1. Run based policy  $\pi_0(\mathbf{a}_t, \mathbf{s}_t)$  to collect  $\mathcal{D} = \{(\mathbf{s}, \mathbf{a}, \mathbf{s}')_i\}$
2. Learn dynamic model  $f(\mathbf{s}, \mathbf{a})$  to minimize  $\sum_i \|f(\mathbf{s}_i, \mathbf{a}_i) - \mathbf{s}'_i\|^2$
3. Plan through  $f(\mathbf{s}, \mathbf{a})$  to choose actions
4. Execute these actions and **add resulting data**  $\{(\mathbf{s}, \mathbf{a}, \mathbf{s}')_j\}$  to  $\mathcal{D}$

**Problems:** the model would learn faster if we correct the mistake more often.

## 8.3 Model-based RL v.1.5

This is much more computational expensive compared to the above.

The more you re-plan, the less perfect each individual plan needs to be  $\Rightarrow$  Can use shorter horizons. ([YouTube](#)).

- 
- every  $N$  steps
1. Run based policy  $\pi_0(\mathbf{a}_t, \mathbf{s}_t)$  to collect  $\mathcal{D} = \{(\mathbf{s}, \mathbf{a}, \mathbf{s}')_i\}$
  2. Learn dynamic model  $f(\mathbf{s}, \mathbf{a})$  to minimize  $\sum_i \|f(\mathbf{s}_i, \mathbf{a}_i) - \mathbf{s}'_i\|^2$
  3. Plan through  $f(\mathbf{s}, \mathbf{a})$  to choose actions
  4. Execute the first planned action, observe resulting state  $\mathbf{s}'$  (**MPC**)
  5. Append  $\{(\mathbf{s}, \mathbf{a}, \mathbf{s}')_j\}$  to  $\mathcal{D}$

**NOTE:** These are all *open-loop planning*, either stochastic or deterministic, algorithms. In other words, in step 3, given a single current state, we do the planning and output a sequence of actions  $\{\mathbf{a}_t, \dots, \mathbf{a}_{t+T}\}$ . Possible planning algorithms are presented in Sec. 7, e.g., random shooting, **CEM**, **MCTS**, **LQR**.

## 8.4 Uncertainty-aware Model

**Problem** of Model-based **RL** v.1.5 (Subsec. ??): overfitting early, especially with high-dimensional data

**Solution:** Introduce **uncertainty estimation**

Step 3. Take action with **high expected reward**

This goes against exploration, thus depends on problems, use different strategies:

- expected value planning
- optimistic value planning
- pessimistic value planning

## 8.5 Uncertainty-Aware Neural Net Models

There are two kinds of uncertainty:

- *aleatoric* uncertainty (statistical data uncertainty)
- *epistemic* uncertainty (model uncertainty)

"The model is certain about the data, but we are not certain about the model".

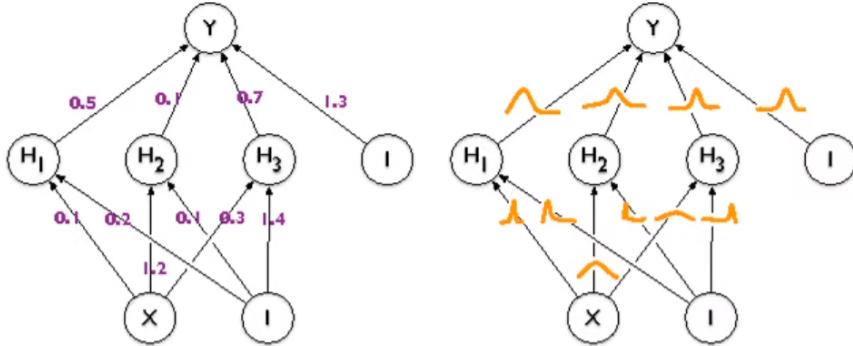

Model uncertainty is then the uncertainty about **params.**  $\theta$  that represents the model. Usually, we estimate:

$$\arg \max_{\theta} \log p(\theta | \mathcal{D}) = \arg \max_{\theta} \log p(\mathcal{D} | \theta)$$

Or estimate the exact  $p(\theta | \mathcal{D})$ , then predict according to  $\int p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t, \theta) p(\theta | \mathcal{D}) d\theta$

- Use output entropy  $p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t)$ : predicts aleatoric uncertainty, which is the wrong one.  
Thus, it's **bad, not going to work.**

- Bayesian neural network: **complicate** [BCK+15], [GHK17].

**Figure 8.1:** Normal neural network (left) and Bayesian neural network (right).

$$p(\theta|\mathcal{D}) = \prod_i p(\theta_i|\mathcal{D}) \quad \text{common approximation} \quad (8.1)$$

$$p(\theta_i|\mathcal{D}) = \mathcal{N}(\mu_i, \sigma_i) \quad \text{common choice for each marginal prob.} \quad (8.2)$$

- Bootstrap ensembles: train ensemble of models (Sec. ??). Each model (usually < 10 models) with **params**.  $\theta_i$  is trained on a dataset  $\mathcal{D}_i$ , which is sampled with replacement from  $\mathcal{D}$ .

$$p(\theta|\mathcal{D}) \approx \frac{1}{N} \sum_i \delta(\theta_i) \quad \text{mixture of delta func.} \quad (8.3)$$

$$\int p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t, \theta) p(\theta|\mathcal{D}) d\theta \approx \frac{1}{N} \sum_i p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t, \theta) \quad (8.4)$$

## 8.6 Planning with Uncertainty

As mentioned before, the model uncertainty is used in step 3 of the model-based **RL** algorithm (Subsec. 8.4). The change is about the reward function that we use to do optimal control for action planning:

- Before:  $J(\mathbf{a}_1, \dots, \mathbf{a}_H) = \sum_{t=1}^H r(\mathbf{s}_t, \mathbf{a}_t)$  where  $\mathbf{s}_{t+1} = f(\mathbf{s}_t, \mathbf{a}_t)$
- Now:  $J(\mathbf{a}_1, \dots, \mathbf{a}_H) = \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^H r(\mathbf{s}_{t,i}, \mathbf{a}_{t,i})$  where  $f(\mathbf{s}_{t,i}, \mathbf{a}_t) = \mathbf{s}_{t+1,i}$  (deterministic case)

General procedure for candidate action sequence  $\mathbf{a}_1, \dots, \mathbf{a}_H$ :

1. Sample  $\theta \sim p(\theta|\mathcal{D})$
2. At each time step  $t$ , sample  $\mathbf{s}_{t+1} \sim p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t, \theta)$
3. Calculate  $R = \sum_t r(\mathbf{s}_t, \mathbf{a}_t)$
4. Repeat step 1 → 3 and accumulate the average reward

# 9 Model-based RL with Images

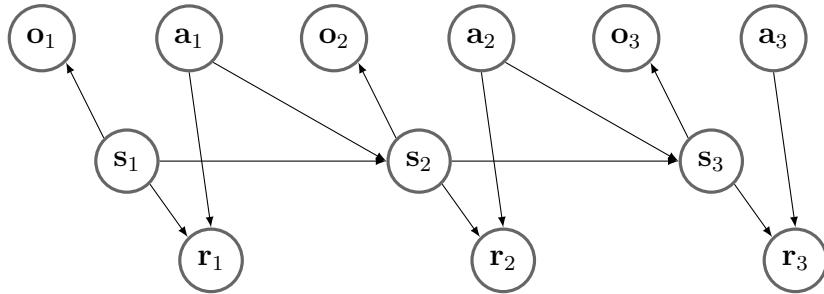

## 9.1 Latent Space Models

In state space (latent-space) models, the inputs are given observations, not states.

$$p(\mathbf{o}_t | \mathbf{s}_t) \quad \text{- observation model: high-dimensional, but not dynamic} \quad (9.1)$$

$$p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \quad \text{- dynamics model: low-dimensional, but dynamic} \quad (9.2)$$

$$p(r_t | \mathbf{s}_t, \mathbf{a}_t) \quad \text{- reward model} \quad (9.3)$$

With the above state space model, we now learn a different model:

- Before: standard (fully observable) model

$$\max_{\phi} \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \log p_{\phi}(\mathbf{s}_{t+1,i} | \mathbf{s}_{t,i}, \mathbf{a}_{t,i})$$

- Now: latent space model

$$\max_{\phi} \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \mathbb{E} [\log p_{\phi}(\mathbf{s}_{t+1,i} | \mathbf{s}_{t,i}, \mathbf{a}_{t,i}) + \log p_{\phi}(\mathbf{o}_{t,i} | \mathbf{s}_{t,i})]$$

the expectation with regard to  $(\mathbf{s}_t, \mathbf{s}_{t+1}) \sim p(\mathbf{s}_t, \mathbf{s}_{t+1} | \mathbf{o}_{1:T}, \mathbf{a}_{1:T})$  (**very complicate**)

The above objective can be learned by the approximate posterior  $q_{\psi}(\mathbf{s}_t | \mathbf{o}_{1:t}, \mathbf{a}_{1:t})$  "**encoder**". There are also other choices for approximate posterior, depending on each problem settings:

$q_{\psi}(\mathbf{s}_t, \mathbf{s}_{t+1}   \mathbf{o}_{1:T}, \mathbf{a}_{1:T})$	full smoothing posterior	+most accurate -most complicated (big RNN)
$q_{\psi}(\mathbf{s}_t   \mathbf{o}_t)$	single-step encoder	+simplest -least accurate (CNN)

- If the situation is more partially observed, you would want a more accurate approximation.
- If the state can be entirely guessed by one single current observation, then this single-step posterior is a good choice.

## 9.2 Deterministic Single-Step Encoder

Simple special case:  $q(\mathbf{s}_t, \mathbf{o}_t)$  is deterministic

$$q_\psi(\mathbf{s}_t | \mathbf{o}_t) = \delta(\mathbf{s}_t = g_\psi(\mathbf{o}_t)) \Rightarrow \mathbf{s}_t = g_\psi(\mathbf{o}_t) \quad \text{deterministic encoder} \quad (9.4)$$

⇒ The goal for model-based RL with latent space is now:

$$\max_{\phi, \psi} \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \log p_\phi [g_\psi(\mathbf{o}_{t+1,i}) | g_\psi(\mathbf{o}_{t,i}), \mathbf{a}_{t,i}] + \log p_\phi [\mathbf{o}_{t,i} | g_\psi(\mathbf{o}_{t,i})] \quad (9.5)$$

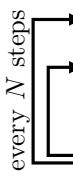

$$\max_{\phi, \psi} \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \log p_\phi [g_\psi(o_{t+1,i}) | g_\psi(o_{t,i}), a_{t,i}] + \log p_\phi [o_{t,i} | g_\psi(o_{t,i})] + \log p_\phi [r_{t,i} | g_\psi(o_{t,i})]$$

## latent space dynamics      image reconstruction      reward model

### 9.3 Model-based RL with Latent Space Model

This is the model-based RL with latent space model, assuming deterministic observation model:

1. Run based policy  $\pi_0(\mathbf{a}_t|\mathbf{o}_t)$  (e.g., random policy) to collect  $\mathcal{D} = \{(\mathbf{o}, \mathbf{a}, \mathbf{o}')_i\}$
  2. Learn  $p_\phi(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t), p_\phi(r_t, \mathbf{s}_t), p(\mathbf{o}_t|\mathbf{s}_t), g_\psi(\mathbf{o}_t)$
  3. Plan through the model to choose actions (e.g., MCTS, LQR, random shooting)
  4. Execute the first planned action, observe result  $\mathbf{o}'$  (MPC)
  5. Append resulting  $(\mathbf{o}, \mathbf{a}, \mathbf{o}')$  to  $\mathcal{D}$

## 9.4 Learning in Observation Space

In some situations, there are too many objects, thus, it's complicated to learn/build a compact state space. The better solution would be to directly learn  $p(\mathbf{o}_{t+1}|\mathbf{o}_t, \mathbf{a}_t)$  (taken in image → split out image).

Gigantic model: RNN. [TODO: ??]

# 10 Model-Based Policy Learning

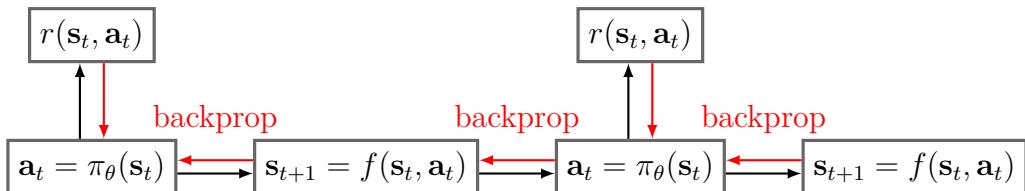

As mentioned before, model-based RL v.1.5 algorithm (Sec. 8.3) is a **stochastic open-loop** algorithm. The agent does see the next state, but it doesn't able to reason about the fact that more information will be available and make use out it. It simply plans the whole action sequence at each time step and assumes that it has to commit to that complete action plan. This is, in most case, **sub-optimal**. This section describes the **closed-loop** case, implying the agent aware that it will be able to see the state feedback and act upon it. Thus, instead of a complete action plan, the output is now a policy  $\pi(\mathbf{a}_t|\mathbf{s}_t)$ .

- Stochastic open-loop case: 
$$\begin{cases} p_{\theta}(\mathbf{s}_1, \dots, \mathbf{s}_T | \mathbf{a}_1, \dots, \mathbf{a}_T) = p(\mathbf{s}_1) \prod_{t=1}^T p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \\ \mathbf{a}_1, \dots, \mathbf{a}_T = \arg \max_{\mathbf{a}_1, \dots, \mathbf{a}_T} \mathbb{E} \left[ \sum_t r(\mathbf{s}_t, \mathbf{a}_t) | \mathbf{a}_1, \dots, \mathbf{a}_T \right] \end{cases}$$
- Stochastic closed-loop case: 
$$\begin{cases} p(\mathbf{s}_1, \mathbf{a}_1, \dots, \mathbf{s}_T, \mathbf{a}_T) = p(\mathbf{s}_1) \prod_{t=1}^T \pi(\mathbf{a}_t | \mathbf{s}_t) p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \\ \pi = \arg \max_{\pi} \mathbb{E}_{\tau \sim p(\tau)} \left[ \sum_t r(\mathbf{s}_t, \mathbf{a}_t) \right] \end{cases}$$

For the above policy  $\pi$ , there are possibly different forms for it:

- Neural net: **global policy**, which would tell us what to do regardless of the state the agent is in the whole state space.
- Time-varying linear  $\mathbf{K}_t \mathbf{s}_t + \mathbf{k}_t$ : **local policy**, which would be simple but only sufficient around particular area of a known trajectory

## 10.1 Model-based RL v.2.0

1. Run based policy  $\pi_0(\mathbf{a}_t, \mathbf{s}_t)$  to collect  $\mathcal{D} = \{(\mathbf{s}, \mathbf{a}, \mathbf{s}')_i\}$
2. Learn dynamic model  $f(\mathbf{s}, \mathbf{a})$  to minimize  $\sum_i \|f(\mathbf{s}_i, \mathbf{a}_i) - \mathbf{s}'_i\|^2$
3. Back-propagate through  $f(\mathbf{s}, \mathbf{a})$  into the policy to optimize  $\pi_\theta(\mathbf{a}_t, \mathbf{s}_t)$
4. Run  $\pi_\theta(\mathbf{a}_t, \mathbf{s}_t)$ , appending the tuples  $(\mathbf{s}, \mathbf{a}, \mathbf{s}')$  to  $\mathcal{D}$

**Problem:**

- Similar parameter sensitivity problems as shooting methods  
The first action is way more important than the later ones.
- Similar problems to training long RNNs with Backpropagation through time (BPTT)  
Vanishing and exploding gradients

⇒ ***Solutions:***

- Use derivative-free ("model-free") planning algorithms with the model used to generate synthetic samples  
E.g.: Policy gradients have high variance, which can be reduced with lots of data, which can be generated by learned model
- Use simpler policies than neural nets
  - LQR with learned models (LQR-Fitted Local Model (FLM))
  - Train **local** policies to solve simple tasks
  - Combine them into **global** policies via supervised learning

## 10.2 Model-Free Learning With a Model

This is one of the solutions for Model-based RL v.2.0 (Sec. 10.1): use the learned model to generate synthetic data for "model-free" RL algorithms, e.g., policy gradient. [PRP+18]

**"Classic" Dyna** [Sut90]: online Q-learning algor. that performs model-free RL with a model

1. Given state  $s$ , pick action  $a$  using exploration policy
2. Observe  $s'$  and  $r$ , to get transition  $(s, a, s', r)$
3. Update model  $\hat{p}(s'|s, a)$  and  $\hat{r}(s, a)$  using  $(s, a, s')$
4. Q-update:  $Q(s, a) \leftarrow Q(s, a) + \alpha \mathbb{E}_{s', r} [r + \max_{a'} Q(s', a') - Q(s, a)]$
5. Repeat  $K$  times:
  - 6. Sample  $(s, a) \sim \mathcal{B}$  from buffer of past states and actions
  - 7. Q-update:  $Q(s, a) \leftarrow Q(s, a) + \alpha \mathbb{E}_{s', r} [r + \max_{a'} Q(s', a') - Q(s, a)]$

***General "Dyna-style" model-based RL:***

1. Collect some data, consisting of transitions  $(\mathbf{s}, \mathbf{a}, \mathbf{s}', r)$  (**1-million steps**)
2. Learn model  $\hat{p}(s'|s, a)$  (and optionally,  $\hat{r}(s, a)$ )
3. Repeat  $K$  times:
  4. Sample  $s \sim \mathcal{B}$  from buffer
  5. Choose action  $a$  (from  $\mathcal{B}$ , from  $\pi$ , or random)
  6. Simulate  $s' \sim \hat{p}(s'|s, a)$  (and  $r = \hat{r}(s, a)$ )
  7. Train on  $(s, a, s', r)$  with model-free RL
  8. (optional) Take  $N$  more model-based steps

The above approach is:

- +only requires short (as few as one step) rollouts from model
- +still sees diverse states

**Problem:** if your model is inaccurate (which always is), the longer we roll-out the model, the more these errors compound. This leads to distribution shift, either in the model or the policy. This is also why this is suited for mostly short rollouts of the model.  $\Rightarrow$  Not very nice for Policy Gradients, but is okay for value-based approaches, actor-critic, etc.

### Note:

- In Classic Dyna, step 5 is to choose action from buffer
- This general procedure is the basis for:
  - Model-based Acceleration (**MBA**) [[GLS+16](#)]
  - Model-based Value Expansion (**MVE**) [[FWS+18b](#)]
  - Model-based Policy Optimization (**MBPO**) [[JFZ+19](#)]

## 10.3 Local Models

This is the second solution for model-based [RL v.2.0](#) (Sec. 10.1): instead of using neural network, we use simple policies, which is time-varying linear controller, i.e., [LQR-FLM](#).

In order to use [LQR](#) (Sec. 7.2), we need  $\frac{df}{d\mathbf{x}_t}, \frac{df}{d\mathbf{u}_t}, \frac{dc}{d\mathbf{x}_t}, \frac{dc}{d\mathbf{u}_t}$ , in which, knowing the model would give us  $\frac{df}{d\mathbf{x}_t}, \frac{df}{d\mathbf{u}_t}$ . If continuous system sufficiently smooth and initial state distribution quite tight  $\Rightarrow$  do linearization regression at every time step

$\Rightarrow$  **Idea:** fit  $\frac{df}{d\mathbf{x}_t}$  and  $\frac{df}{d\mathbf{u}_t}$  around current trajectory / policy

### LQR-FLM Algorithm:

- 1. Run  $p(\mathbf{u}_t|\mathbf{x}_t)$  on robot, collect  $\mathcal{D} = \{\tau_i\}$   
 2. Fit dynamics  $p(\mathbf{x}_{t+1}|\mathbf{x}_t, \mathbf{u}_t)$

$$p(\mathbf{x}_{t+1}|\mathbf{x}_t, \mathbf{u}_t) = \mathcal{N}(f(\mathbf{x}_t, \mathbf{u}_t), \Sigma)$$

$$f(\mathbf{x}_t, \mathbf{u}_t) \approx \mathbf{A}_t \mathbf{x}_t + \mathbf{B}_t \mathbf{u}_t$$

$$\mathbf{A}_t = \frac{df}{d\mathbf{x}_t} \quad \mathbf{B}_t = \frac{df}{d\mathbf{u}_t}$$

3. Improve controller  $p(\mathbf{u}_t|\mathbf{x}_t)$  ([LQR](#))

### Which controller to run? $p(\mathbf{u}_t|\mathbf{x}_t)$

- Version 0.5:  $p(\mathbf{u}_t|\mathbf{x}_t) = \delta(\mathbf{u}_t = \hat{\mathbf{u}}_t)$  doesn't correct deviations or drift

- Version 1.0:  $p(\mathbf{u}_t|\mathbf{x}_t) = \delta \mathbf{u}_t = \mathbf{K}_t(\mathbf{x}_t - \hat{\mathbf{x}}_t) + \mathbf{k}_t + \hat{\mathbf{u}}_t$

Better, but a little too good. When fitting the dynamics, we need data to be a little bit cluster, but not too much. **Still need to be varied, for exploration and fitting.**

- Version 2.0:  $p(\mathbf{u}_t|\mathbf{x}_t) = \mathcal{N}(\mathbf{K}_t(\mathbf{x}_t - \hat{\mathbf{x}}_t) + \mathbf{k}_t + \hat{\mathbf{u}}_t, \Sigma_t)$

Set  $\Sigma_t = \mathbf{Q}_{\mathbf{u}_t, \mathbf{u}_t}^{-1}$

**How to fit the dynamics?**  $p(x_{t+1}|x_t, u_t)$  given  $\{(\mathbf{x}_t, \mathbf{u}_t, \mathbf{x}_{t+1})_i\}$

- Version 1.0: At each time step using linear regression

$$p(\mathbf{x}_{t+1}|\mathbf{x}_t, \mathbf{u}_t) = \mathcal{N}(\mathbf{A}_t \mathbf{x}_t + \mathbf{B}_t \mathbf{u}_t + \mathbf{c}, \mathbf{N}_t); \quad \mathbf{A}_t \approx \frac{df}{d\mathbf{x}_t}; \mathbf{B}_t \approx \frac{df}{d\mathbf{u}_t}$$

**Problems:** linear regression requires number of samples that scale with dimensional states

- Version 2.0: fit using Bayesian linear regression

Use your favorite global model as prior

⇒ Can get away with fewer samples

**How to stay close to old controller?**

We want to stay close around local region of trajectories where we have linearized approximation

⇒ Keep **KL** divergence small (between old and new trajectories) [LA14]

$$p(\mathbf{u}_t|\mathbf{x}_t) = \mathcal{N}(\mathbf{K}_t(\mathbf{x}_t - \hat{\mathbf{x}}_t) + \mathbf{k}_t + \hat{\mathbf{u}}_t, \Sigma_t) \quad \text{the controller} \quad (10.1)$$

$$p(\tau) = p(\mathbf{x}_1) \prod_{t=1}^T p(\mathbf{u}_t|\mathbf{x}_t)p(\mathbf{x}_{t+1}|\mathbf{x}_t, \mathbf{u}_t) \quad \text{the resulting trajectory} \quad (10.2)$$

$$D_{KL}(p(\tau)||\bar{p}(\tau)) \leq \epsilon \quad \text{constraint on KL divergence} \quad (10.3)$$

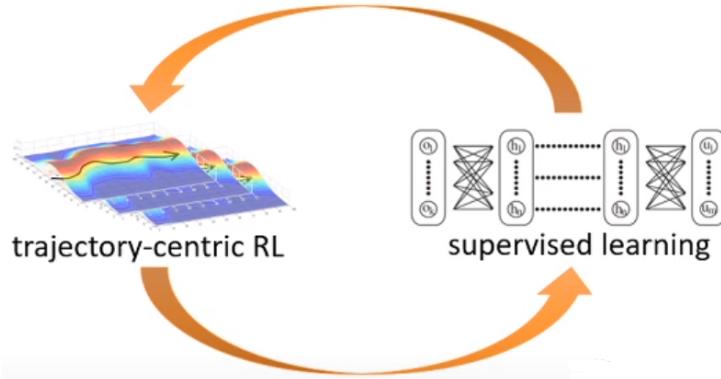

## 10.4 Guided Policy Search

This is the extension of local policies to global policies. However, the idea behind this, which is similar to distillation of ensemble (Sec. 5.8, [AI notes](#)), is also important in other settings.

Given many local policies, we take the data from these local policies and treat them as expert's demonstrations and combine them into a global policy. The global policy can be learned as a neural net with supervised learning from these local data.

**Guided Policy Search Algorithm:** [\[LFD+16\]](#)

1. Optimize each local policy  $\pi_{LQR,i}(\mathbf{u}_t|\mathbf{x}_t)$  on initial state  $\mathbf{x}_{0,i}$ , **w.r.t.**  $\tilde{c}_{k,i}(\mathbf{x}_t, \mathbf{u}_t)$
  2. Use samples from step (1) to train  $\pi_\theta(\mathbf{u}_t|\mathbf{x}_t)$  to mimic all  $\pi_{LQR,i}(\mathbf{u}_t|\mathbf{x}_t)$
  3. Update cost function  $\tilde{c}_{k+1,i}(\mathbf{x}_t, \mathbf{u}_t) = c(\mathbf{x}_t, \mathbf{u}_t) + \lambda_{k+1,i} \log \pi_\theta(\mathbf{u}_t|\mathbf{x}_t)$

**Figure 10.1:** Guided policy search: algorithm sketch ([src](#)).

in which,  $i$  indexes the initial state and the local solution,  $k$  the iteration,  $\tilde{c}_{k,i}(\mathbf{x}_t, \mathbf{u}_t)$  is the modified cost, including the task reward, and the **KL** between  $\pi_{LQR,i}$  and  $\pi_\theta PP$

#### Divide and Conquer **RL** algorithm:

- 1. Optimize each local policy  $\pi_{\theta,i}(\mathbf{u}_t|\mathbf{x}_t)$  on initial state  $\mathbf{x}_{0,i}$ , w.r.t.  $\tilde{r}_{k,i}(\mathbf{x}_t, \mathbf{u}_t)$
- 2. Use samples from step (1) to train  $\pi_\theta(\mathbf{u}_t|\mathbf{x}_t)$  to mimic all  $\pi_{\theta,i}(\mathbf{u}_t|\mathbf{x}_t)$
- 3. Update cost function  $\tilde{r}_{k+1,i}(\mathbf{x}_t, \mathbf{u}_t) = r(\mathbf{x}_t, \mathbf{u}_t) + \lambda_{k+1,i} \log \pi_\theta(\mathbf{u}_t|\mathbf{x}_t)$

# 11 Exploration

## 11.1 Overview

In the setting of delayed reward, not knowing which actions would give more reward, we would want the agent to *explore*. The concerns are:

- How can an agent discover high-reward strategies that require a temporally extended sequence of complex behaviors that, individually, are not rewarding?
- How can an agent decide whether to attempt new behaviors (to discover ones with higher reward) or continue to do the best things it knows so far?

This poses a exploration and exploitation dilemma:

- *Exploration*: doing things you haven't done before, in the hopes of getting even higher reward
- *Exploitation*: doing what you know will yield the highest reward

### 11.1.1 Regret

Exploration can be viewed as a POMDP. Solving the POMDP to know the exact underlying distribution is overkill. We instead want a simpler strategy that is not too bad from the optimal ones. The *regret* is the metric to measure how good or bad an exploration strategy.

**Definition:** *Regret* is the reward difference from optimal policy at time step  $T$ :

$$\underbrace{\text{Reg}(T)}_{\text{regret at } T} = T \cdot \underbrace{\mathbb{E}[r(a^*)]}_{\text{expected reward of the best action}} - \underbrace{\sum_{t=1}^T r(a_t)}_{\text{the actual sum of reward}}$$

**Example:** Consider the following multi-armed bandit problem:

A professor moves to a small town for work. He will stay there for 300 days. Each day, he will eat at one of three restaurants in the town. Eating at each restaurant has a different happiness distribution. Let say, the happiness distributions of each restaurant are as follows:

- Restaurant 1:  $\mu = 10, \sigma = 5$
- Restaurant 2:  $\mu = 8, \sigma = 8$
- Restaurant 3:  $\mu = 5, \sigma = 25$

Not knowing the true happiness distribution, which strategy should the professor follow to maximize the expected happiness score?

The regrets for some exploration strategies:

- Optimal reward: Knowing the true distribution, the optimal action is to always go to restaurant 1.

$$\mathbb{E}[r] = 300 \times 10 = 3000$$

- Explore only: the professor spends 100 days at each restaurant.

$$\mathbb{E}[r] = 100 \times 10 + 100 \times 8 + 100 \times 5 = 2300$$

$$\Rightarrow \rho = 3000 - 2300 = 700 \quad (\text{regret})$$

- Exploit only: visit each restaurant once, then stick with the one with the highest value. Assume the receive reward after 3 days are:  $r_1 = 7, r_2 = 8, r_3 = 5$ . After that, the expected reward would be:

$$\mathbb{E}[r] = 7 + 8 + 5 + (300 - 3) \times 8 = 2396$$

However, this is not the actual expected reward for the exploit only strategy.

$$\rho = 3000 - 2670 = 330$$

- Zero regret strategy: As time goes on  $T \rightarrow \infty$ , the regret will approach to 0  $\rho \rightarrow 0$

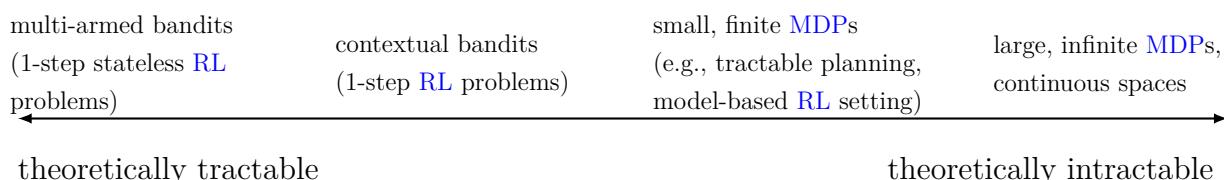

### 11.1.2 Optimality

*Optimality:* An exploration strategy is *optimal* when we compared the regret **vs.** the Bayes-optimal strategy. [TODO:]

[TODO: Optimal exploration in small MDPs]

### 11.1.3 Tractability

- With *theoretically tractable* exploration strategy, we can quantify or understand whether the given exploration strategy is optimal or sub-optimal
  - With *theoretically intractable* exploration strategy, we cannot make the above estimate exactly.

- multi-armed bandits: can formalize exploration as POMDP identification
- contextual bandits: policy learning is trivial even with POMDP
- small, finite MDPs: can frame as Bayesian model identification, reason explicitly about value of information
- large or infinite MDPs: optimal methods don't work, but can take inspiration from optimal methods in smaller settings

## 11.2 Bandits Problems

### 11.2.1 One-Armed Bandit

One armed bandit is the slot machine. It can be represent as a MDP with one single action. The prob. distribution of the reward is unknown.

$$\mathcal{A} = \{\text{pull arm}\} \quad (11.1)$$

$$r(\text{pull arm}) = ? \quad (11.2)$$

**Figure 11.1:** One-armed bandit ([src](#)).

### 11.2.2 Multi-Armed Bandit

Multi armed bandit is a bank of multiple one-armed bandit slot machines. This problem is a 1-step stateless MDP. Different machines have different reward distributions, which are unknown, but can be learned by trials.

$$\mathcal{A} = \{\text{pull}_1, \text{pull}_2, \dots, \text{pull}_n\} \quad (11.3)$$

$$r(a_n) = ? \quad (11.4)$$

$$\text{assume } r(a_n) \sim p(r|a_n) \quad (11.5)$$

We can define the bandits as a POMDP with the state as params. that represents the reward models. Solving the POMDP leads to the optimal exploration strategy.

$$\mathbf{s} = [\theta_1, \dots, \theta_n]$$

But the belief state of  $\theta$  is large, thus, doing this is overkill. We can do well with simpler strategies.

### 11.2.3 Contextual Bandits

- the reward distribution depends on some external measurable variable.
- bandits with state, essentially 1-step MDP
- [TODO: ]

### 11.2.4 Bandit Variants

- Infinite Arms: there are more slot machines.
- Variable Arms: the reward distribution varies for each slot machine.
- Combinatorial Bandits: the agent has to pull more than one arm at once.
- Dueling Bandits: agent always pulls two arms, is never told about the reward, ...
- Continuous Bandits: agent has to choose interval value, like the force to the arm.
- Adversarial Arms: the agent plays against an opponent. Thus if the agent uses the same strategy, the opponent will adapt, and the Q-value of that action will change over time.  
E.g.: chess, tic-tac-toe.
- Strategic Arms
- and more!

### 11.2.5 Gradient Bandits

[TODO: ]

### 11.2.6 Applications

There are various applications in:

- Ad serving: arms - possible ads, reward - a click
- Website optimization: arms: possible website options, reward - user engagement
- Clinical trials: arms: possible medications, reward - health outcomes

### 11.3 Exploration Strategies for Bandits Problem

#### 11.3.1 $\epsilon$ -first

[TODO: ]

#### 11.3.2 $\epsilon$ -greedy

[TODO: formula]

With the example in Sec. 11.1.1, assuming  $\epsilon = 10\%$ , the professor spend 10% of the days (30 days) to try non-optimal restaurants, and the rest to exploit the current belief about the best restaurant.

$$\rho \approx 100$$

#### 11.3.3 Optimistic Exploration

The high-level idea is to try each arm until you are sure it's not great.

- Keep track of average reward  $\hat{\mu}_a$  for each action  $a$
- Optimistic estimate:  $a = \arg \max_a [\hat{\mu}_a + C\sigma_a]$ .  
Choose the action with either current high average reward, or with high covariance  $\sigma_a$

Upper Confidence Bound (UCB):

$$A_t = \arg \max_a \left[ Q_t(a) + c \sqrt{\frac{\ln t}{N_t(a)}} \right], \quad \begin{cases} Q_t(a) - \text{current reward belief} \\ N_t(a) - \text{no. times taking action } a \\ t - \text{current no. time step} \end{cases}$$

UCB-1 use Chernoff - Hoeffding Inequality, with  $Reg(T) = \mathcal{O}(\log T)$ :

$$C_j(t) = \sqrt{\frac{\log(n)}{T_j(t)}}$$

$$a = \arg \max_a \left[ \hat{\mu}_a + \sqrt{\frac{2 \ln T}{N(a)}} \right]$$

NOTE:

- lots of other functions work as well, as long as they decrease with  $N(a)$
- UCB is more difficult than  $\epsilon$ -greedy to extend beyond bandits to more general RL problems (nonstationary problems, large state spaces)

### 11.3.4 Probability Matching / Posterior Sampling

Optimistic strategy doesn't try to model the uncertainty. It is model-free approach, simply keeps the average rewards and the number of times an action is taken. For the multi bandits problem, assuming some reward model  $r(a_i) \sim p_{\theta_i}(r_i)$ , we could instead keep a belief  $\hat{p}(\theta_1, \dots, \theta_n)$  over the [params.](#) and solve the [POMDP](#) with  $\mathbf{s} = [\theta_1, \dots, \theta_n]$ .

**Idea:** Thompson sampling [CL11]

- 1. Sample  $\theta_1, \dots, \theta_n \sim \hat{p}(\theta_1, \dots, \theta_n)$
- 2. Pretend the model  $\theta_1, \dots, \theta_n$  is correct
- 3. Take the optimal action  $a = \arg \max_a \mathbb{E}_{\theta_a}[r(a)]$
- 4. Update the model
  - Harder to analyze theoretically
  - Can work very well empirically

### 11.3.5 Information Gain

This method is even more explicitly model-based.

**Bayesian experimental design:** aim to determine some unknown latent variable  $z$  but can only take actions to learn about it.

$\mathcal{H}(\hat{p}(z))$	– the current entropy of $z$ estimate
$\mathcal{H}(\hat{p}(z) y)$	– the entropy of $z$ estimate after observation $y$
$IG(z, y) = \mathbb{E}_y [\mathcal{H}(\hat{p}(z)) - \mathcal{H}(\hat{p}(z) y)]$	– the <i>information gain</i> about $z$ after $y$
$IG(z, y a) = \mathbb{E}_y [\mathcal{H}(\hat{p}(z)) - \mathcal{H}(\hat{p}(z) y) a]$	– usually condition on action $a$

- e.g.,  $y$  might be optimal action  $a^*$  or the reward  $r(a)$ )
- We want to take actions and receive  $y$  such that we get high Information Gain ([IG](#)) about  $z$

E.g., bandit [algor.](#) [RVR14]:

$$y = r_a \quad \text{– reward for action } a \quad (11.6)$$

$$z = \theta_a \quad \text{– } \text{params.} \text{ of model } p(r_a) \quad (11.7)$$

$$g(a) = IG(\theta_a, r_a|a) \quad \text{– information gain of } a \quad (11.8)$$

$$\Delta(a) = \mathbb{E}[r(a^*) - r(a)] \quad \text{– expected suboptimality of } a \quad (11.9)$$

$$\Rightarrow a = \arg \min_a \frac{\Delta(a)^2}{g(a)} \quad (11.10)$$

the high-level idea is to take the least suboptimal action that give us more information.

[TODO: Bayesian Model-based **RL**]

[TODO: Probably Approximately Correct (**PAC**) exploration]

## 11.4 Exploration Strategies in RL

### 11.4.1 Information Theoretic Quantities in RL

$\pi(\mathbf{s}) = p_\pi(\mathbf{s})$	– state <i>marginal</i> distribution of policy $\pi$
$\mathcal{H}(\pi(\mathbf{s}))$	– state <i>marginal</i> entropy of policy $\pi$
$\mathcal{I}(\mathbf{x}; \mathbf{y}) = D_{KL}(p(\mathbf{x}, \mathbf{y})    p(\mathbf{x})p(\mathbf{y}))$	– mutual information ( <a href="#">math notes</a> )
$\mathcal{I}(\mathbf{s}_{t+1}; \mathbf{a}_t) = \mathcal{H}(\mathbf{s}_{t+1}) - \mathcal{H}(\mathbf{s}_{t+1}   \mathbf{a}_t)$	– <i>empowerment</i>

**Intuition:** we want a large empowerment because: A large entropy  $\mathcal{H}(\mathbf{s}_{t+1})$  implies that there are many possible next states. A small entropy  $\mathcal{H}(\mathbf{s}_{t+1} | \mathbf{a}_t)$  implies that given current action, it's easy to determine where the state will landed.

### 11.4.2 Optimistic Exploration in Deep RL

For bandits problem, **UCB** chooses the action with  $a = \arg \max_a \hat{\mu}_a + \sqrt{\frac{2 \ln T}{N(a)}}$  (Subsec. 11.3.3). The term  $\sqrt{\frac{2 \ln T}{N(a)}}$  can be considered as "exploration bonus". Lots of functions work, as long as they decrease with the count  $N(a)$ .

For **MDPs**, we use similar state counts  $N(\mathbf{s}, \mathbf{a})$  or  $N(\mathbf{s})$  to add *exploration bonus*:

$$r^+(\mathbf{s}, \mathbf{a}) = r(\mathbf{s}, \mathbf{a}) + \mathcal{B}(N(s)) \quad \text{– updated reward function} \quad (11.11)$$

$$\mathcal{B}(N(s)) \quad \text{– bonus that decreases with } N(\mathbf{s}) \quad (11.12)$$

+simple addition to any model-free RL algor.

–need to tune bonus weight

In most settings of continuous state and action space, the agent might not literally visit the exact state again.

⇒ **Pseudo-counts:** to count similar states  $\hat{N}(\mathbf{s})$  or  $\hat{N}(\mathbf{s}, \mathbf{a})$  [[BSO+16](#)]

- 1. fit model  $p_\theta(\mathbf{s})$  to all states  $\mathcal{D}$  seen so far
- 2. take a step  $i$  and observe  $\mathbf{s}_i$
- 3. fit new model  $p_{\theta'}(\mathbf{s})$  to  $\mathcal{D} \cup \mathbf{s}_i$
- 4. use  $p_\theta(\mathbf{s}_i)$  and  $p_{\theta'}(\mathbf{s}_i)$  to estimate  $\hat{N}(\mathbf{s})$
- 5. set  $r_i^+ = r_i + \mathcal{B}(\hat{N}(\mathbf{s}))$

$$\hat{N}(\mathbf{s}_i) = \hat{n} p_\theta(\mathbf{s}_i), \quad \hat{n} = \frac{1 - p_{\theta'}(\mathbf{s}_i)}{p_{\theta'}(\mathbf{s}_i) - p_\theta(\mathbf{s}_i)} p_\theta(\mathbf{s}_i)$$

**Types of exploration bonus:**

- UCB:  $\mathcal{B}(N(\mathbf{s})) = \sqrt{\frac{2 \ln n}{N(\mathbf{s})}}$  (11.13)

- MBIE-EB: [SL08; BSO+16]  $\mathcal{B}(N(\mathbf{s})) = \sqrt{\frac{1}{N(\mathbf{s})}}$  (11.14)

- BEB: [KN09]  $\mathcal{B}(N(\mathbf{s})) = \frac{1}{N(\mathbf{s})}$  (11.15)

**Kind of model:**  $p_\theta(\mathbf{s})$  need to output densities, but not necessarily produce great samples

- CTS model [BSO+16]
- stochastic neural networks
- compression length
- EX2

There are similar count style approaches:

- Counting with hashes: counts states but in different space [THF+17].
- Implicit density modeling with exemplar models: Use a classifier to classify whether a state is **novel** or not. [FCRL17]
- Heuristics estimation of counts via errors: Given buffer  $\mathcal{D} = \{(\mathbf{s}_i, \mathbf{a}_i)\}$ 
  - Fit  $\hat{f}_\theta(\mathbf{s}, \mathbf{a})$  to **target** function  $f^*(\mathbf{s}, \mathbf{a})$
  - Use  $\mathcal{E}(\mathbf{s}, \mathbf{a}) = \left\| \hat{f}_\theta(\mathbf{s}, \mathbf{a}) - f^*(\mathbf{s}, \mathbf{a}) \right\|^2$  as exploration bonus

Choice for  $f^*(\mathbf{s}, \mathbf{a})$ : [BES+18]

- $f^*(\mathbf{s}, \mathbf{a}) = \mathbf{s}'$  as next state transition
- $f^*(\mathbf{s}, \mathbf{a}) = f_\phi(\mathbf{s}, \mathbf{a})$ , where  $\phi$  is a **random params.** vector

### 11.4.3 Posterior Sampling in Deep RL

The MDP analog for  $\theta$  of the bandits problem (Subsec. 11.3.4) is the Q-function.

**Idea:**

- 1. sample Q-function  $Q$  from  $p(Q)$   
 2. act according to  $Q$  for one episode  
 3. update  $p(Q)$

**Bootstrapped DQN algorithm:** to represent the distribution of a function [OBP+16]

- given a dataset  $\mathcal{D}$ , resample with replacement  $N$  times  $\rightarrow \mathcal{D}_1, \dots, \mathcal{D}_N$

- train each model  $f_{\theta_i}$  on  $\mathcal{D}$  (**NOTE:** shared network with multi heads)
- to sample from  $p(Q)$ , sample  $i \in [1, \dots, N]$  and use model  $f_{\theta_i}$

+no change to original reward function

-very good bonuses often do better

#### 11.4.4 Information Gain in Deep RL

Extending Subsec. 11.3.5 in the context of deep RL:

- **IG** on reward  $r(\mathbf{s}, \mathbf{a})$ : not very useful if reward is sparse
- **IG** on state density  $p(\mathbf{s})$ : strange, but makes sense!
- **IG** on dynamics  $p(\mathbf{s}'|\mathbf{s}, \mathbf{a})$ : good proxy for learning MDP, though still heuristics
- Generally intractable to use **IG** exactly, thus, we will have to approximate something

Few options for approximation of **IG** are:

- Prediction gain:  $\log p_{\theta'}(\mathbf{s}) - \log p_{\theta}(\mathbf{s})$  [BSO+16]
- Intuition:** if the density change a lot, the state was novel
- Similar to prediction gain, but in feature space: [PAE+17; BEP+18]

$$r_t^i = \frac{\eta}{2} \left\| \hat{\phi}(s_{t+1}) - \phi(s_{t+1}) \right\|_2^2 \quad (11.16)$$

- Variational inference:  $D_{KL}(p(z|y) || p(z))$   
Learn about transitions  $p_{\theta}(s_{t+1}|s_t, a_t)$ , with  $z = \theta$  and  $y = (s_{t+1}|s_t, a_t)$
- $\Rightarrow D_{KL}(p(\theta|h, s_t, a_t, s_{t+1}) || p(\theta|h)) \quad - \text{IG from a new transition} \quad (11.17)$
- $h \quad - \text{history of all prior transitions} \quad (11.18)$

**Intuition:** a transition is more informative if it causes belief over  $\theta$  to change a lot.

**Idea:** [HCD+16]

- Use variational inference to estimate  $q(\theta|\phi) \approx p(\theta|h)$
- Given new transition  $(s, a, s')$ , update  $\phi$  to get  $\phi'$
- Use  $D_{KL}(q(\theta|\phi') || q(\theta|\phi))$  as approximate bonus of **IG**

+appealing mathematical formalism

-models are more complex, generally harder to use effectively

Similar works: exploration with model errors: [Sch10; SLA15]

## 11.5 Unsupervised Learning of Diverse Behaviors

The three above approaches are modifications to existing [RL](#) approaches to boost exploration behaviors, which is in the context of given existing task and reward. This section concerns situations there is no specified task, no sparse or delay reward, but [\*\*no reward at all\*\*](#).

- Learn skills without supervision, then use them to accomplish goals
- Learn sub-skills to use with hierarchical [RL](#)
- Explore the space of possible behaviors

### 11.5.1 Goal-proposed Mechanism

**Intuition:** To prepare for an unknown goal in the future, the robot will have an unsupervised learning phase, in which it trains itself with self-proposed goals. The *goal*, which is to reach an underlying state  $z$ , are inferred from current observation  $x$ , using variational inference models.

**Algorithm:** unsupervised goal-proposed mechanism

1. Propose goal:  $z_g \sim p(z), x_g \sim p_\theta(x_g, z_g)$
  2. Attempt to reach goal using  $\pi(a|x, x_g)$ , reach  $\bar{x}$
  3. Use data to update  $\pi$
  4. Use data to update  $p_\theta(x_g|z_g), q_\phi(z_g|x_g)$

#### **How to have diverse goals?**

The initial policy  $\pi$  might end up with a specific state distribution  $\pi(\mathbf{s}) = p_\pi(\mathbf{s})$ , which is not the marginal state distribution  $p(\mathbf{s}) \neq \pi(\mathbf{s})$ . If we use these samples to update the variational inference model, the model will learn and generate more samples similar to the seen samples. We don't want this to happen, thus, apply exploration ideas. [[NPD+18](#); [PDL+19](#)]

- Standard [MLE](#):  $\theta, \phi \leftarrow \arg \max_{\theta, \phi} \mathbb{E}[\log p(\bar{x})]$
- Weighted [MLE](#):  $\theta, \phi \leftarrow \arg \max_{\theta, \phi} \mathbb{E}[w(\bar{x}) \log p(\bar{x})], \quad w(\bar{x}) = p_\theta(\bar{x})^\alpha, \quad \alpha \in [-1, 0]$

**NOTE:** the goal of unsupervised learning of diverse behaviors

- Updating the variational inference model implies maximizing the entropy  $\mathcal{H}(p(G))$  to have diverse goals
- Updating the policy  $\pi(a|S, G)$  is minimizing  $\mathcal{H}(p(G|S))$ , because as  $\pi$  gets better, the final state  $S$  gets closer to  $G$
- Thus, this algorithm is maximizing the empowerment  $\max \mathcal{I}(S; G)$ , good exploration  $\mathcal{H}(p(G))$  and effective goal reaching  $\mathcal{H}(p(G|S))$ .

### 11.5.2 State Distribution-Matching Formulation

The first three types of [algor.s](#), especially optimistic and [IG](#), have an intrinsic motivation to reward visiting [\*novel\*](#) states by adding an exploration bonus. This bonus concerns with whether the state has been visited *often* before.

$$\tilde{r}(\mathbf{s}) = r(\mathbf{s}) - \log p_\pi(\mathbf{s}) = r(\mathbf{s}) - \log \pi(\mathbf{s}) \quad (11.19)$$

A general procedure could be described as:

- 1. update  $\pi(\mathbf{a}|\mathbf{s})$  to maximize  $\mathbb{E}_\pi[\tilde{r}(\mathbf{s})]$
- └ 2. update  $p_\pi(\mathbf{s})$  to fit state marginal

In the case of unsupervised learning with no reward  $r(\mathbf{s})$ , the goal will then to simply to maximize the exploration bonus  $\tilde{r}(\mathbf{s}) = -\log p_\pi(\mathbf{s})$  (Eq. 11.19).

**Problem:** the state [prob.](#) is under expectation of the current policy  $\pi$ . Thus, the policy  $\pi$  will keep changing to visit states that it hasn't been often before.

**Solution:** the state marginal matching problem - learn  $\pi(\mathbf{a}|\mathbf{s})$  to minimize  $D_{KL}(p_\pi(\mathbf{s})||p^*(\mathbf{s}))$

$$\tilde{r}(\mathbf{s}) = \log p^*(\mathbf{s}) - \log p_\pi(\mathbf{s}) \quad (11.20)$$

- 1. learn  $\pi_k(\mathbf{a}|\mathbf{s})$  to maximize  $\mathbb{E}_\pi[\tilde{r}(\mathbf{s})]$
- └ 2. update  $p_{\pi_k}(\mathbf{s})$  to fit *all states seen so far* (not just the state of the current policy  $\pi_k$ )
- 3. return  $\pi^*(\mathbf{a}|\mathbf{s}) = \sum_k \pi_k(\mathbf{a}|\mathbf{s})$

Proof: [[LEP+19](#); [HKS+19](#)]

### 11.5.3 State Coverage

#### Is coverage of valid states a good exploration objective?

- Skew-Fit:  $\max \mathcal{H}(p(G)) - \mathcal{H}(p(G|S)) = \max \mathcal{I}(S : G)$  [[PDL+19](#)]
- SMM (special case where  $p^*(\mathbf{s}) = C$ ):  $\max \mathcal{H}(p_\pi(S))$  [[LEP+19](#)]

**"Eysenbach's Theorem"**: If at test time, an *adversary* will possibly choose the *hardest/worst* goal  $G$ , which goal distribution should we use for *training*?

**Answer:** Choose  $p(G) = \arg \max_p \mathcal{H}(p(G))$ , which is the uniform distribution to maximize state entropy. [[HKS+19](#); [GEF+18](#)]

#### 11.5.4 Covering the Space of Skills

Reaching diverse **goals** is not the same as performing diverse **tasks**. Not all behaviors can be captured by **goal-reaching**. [GRW16; EGI+18]

**Intuition:** different skills should visit different state-space regions.

$$\pi(\mathbf{a}|\mathbf{s}, z) = \arg \max_{\pi} \sum_z \mathbb{E}_{\mathbf{s} \sim \pi(\mathbf{s}|z)} [r(\mathbf{s}, z)] \quad (11.21)$$

$$r(\mathbf{s}, z) = \log p(z|\mathbf{s}) \quad \text{reward states that are unlikely for other } z' \neq z \quad (11.22)$$

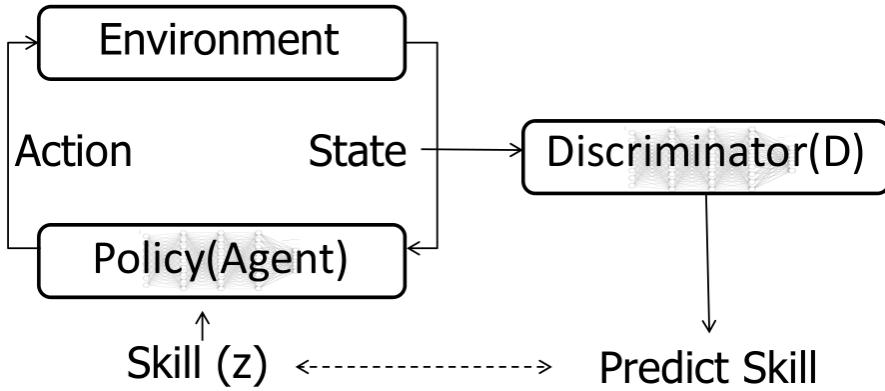

Figure 11.2: Diversity is All You Need. [EGI+18].

#### Connection to mutual information

$$\mathcal{I}(z, \mathbf{s}) = \mathcal{H}(z) - \mathcal{H}(z|\mathbf{s}) \quad (11.23)$$

- $\mathcal{H}(z)$ : maximized by using uniform prior  $p(z)$
- $\mathcal{H}(z|\mathbf{s})$ : minimized by maximizing  $r(\mathbf{s}, z) = \log p(z|\mathbf{s})$

# 12 Control as Inference

- *Inference* means the process of inferring something, or a conclusion reached on the basis of evidence and reasoning.
- *Probabilistic inference* is the task of deriving the **prob.** of one or more random variables taking a specific value or set of values.
- *Variational inference* lets us approximate a high-dimensional Bayesian posterior with a simpler variational distribution by solving an optimization problem.

## 12.1 Probabilistic Graphical Model

Good behavior most of the time has minor mistakes here and there, though overall it is optimal. Thus, good behavior is rather suboptimal. Traditional optimal control doesn't consider stochastic suboptimal behaviors like that.

- Traditional probabilistic model of optimal control

$$\mathbf{a}_1, \dots, \mathbf{a}_T = \arg \max_{\mathbf{a}_1, \dots, \mathbf{a}_T} \sum_{t=1}^T r(\mathbf{s}_t, \mathbf{a}_t)$$

$$\mathbf{s}_{t+1} = f(\mathbf{s}_t, \mathbf{a}_t)$$

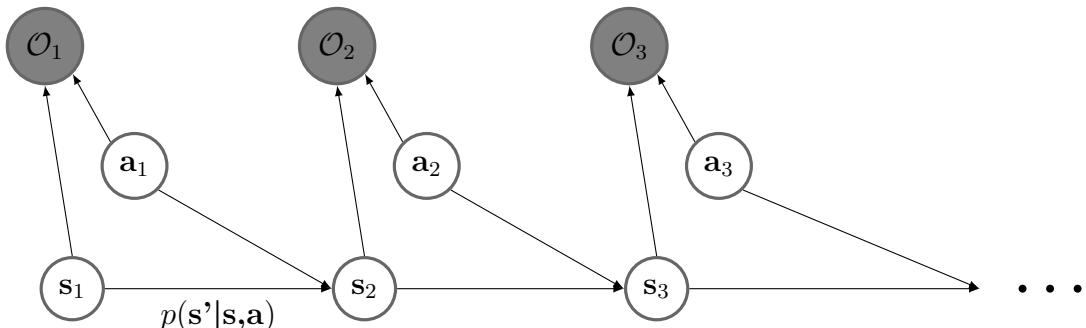

- Probabilistic graphical model:  $\mathcal{O}_t$  as the optimality variable

$$p(\mathbf{s}_{1:T}, \mathbf{a}_{1:T}) = p(\tau) \tag{12.1}$$

$$p(\mathcal{O} | \mathbf{s}_t, \mathbf{a}_t) = \exp(r(\mathbf{s}_t, \mathbf{a}_t)) \tag{12.2}$$

$$p(\tau | \mathcal{O}_{1:T}) = \frac{p(\tau, \mathcal{O}_{1:T})}{p(\mathcal{O}_{1:T})} \tag{12.3}$$

$$\propto p(\tau) \prod_t \exp(r(\mathbf{s}_t, \mathbf{a}_t)) = p(\tau) \exp \left( \sum_t r(\mathbf{s}_t, \mathbf{a}_t) \right) \tag{12.4}$$

## 12.2 Control as Inference

Here, *inference* implies planning. To do inference, we compute the three following terms:

$\beta_t(\mathbf{s}_t, \mathbf{a}_t) = p(\mathcal{O}_{t:T}   \mathbf{s}_t, \mathbf{a}_t)$	– backward messages
$p(\mathbf{a}_t   \mathbf{s}_t, \mathcal{O}_{1:T})$	– policy
$\alpha_t(\mathbf{s}_t) = p(\mathbf{s}_t   \mathcal{O}_{1:t-1})$	– forward messages

### 12.2.1 Backward Messages Computation

Backward messages  $\beta_t(\mathbf{s}_t, \mathbf{a}_t) = p(\mathcal{O}_{t:T} | \mathbf{s}_t, \mathbf{a}_t)$  is the **prob.** of optimality from the current time step  $t$  till the end  $T$ , given the current state.  $\mathbf{s}_t$  and action  $\mathbf{a}_t$ .

$\beta_t(\mathbf{s}_t, \mathbf{a}_t) = p(\mathcal{O}_{t:T}   \mathbf{s}_t, \mathbf{a}_t)$	– the state-action backward message
$\beta_t(\mathbf{s}_t) = p(\mathcal{O}_{t:T}   \mathbf{s}_t)$	– the state backward message

Given:

$p(\mathcal{O}_t   \mathbf{s}_t, \mathbf{a}_t) \propto \exp(r(\mathbf{s}_t, \mathbf{a}_t))$	prob. of current optimality given state and action
$p(\mathbf{s}_{t+1}   \mathbf{s}_t, \mathbf{a}_t)$	transition prob.

Formulation:

$$\beta_t(\mathbf{s}_t, \mathbf{a}_t) = p(\mathcal{O}_{t:T} | \mathbf{s}_t, \mathbf{a}_t) \quad (12.5)$$

$$= \int p(\mathcal{O}_{t:T}, \mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) d\mathbf{s}_{t+1} \quad (12.6)$$

$$= \int p(\mathcal{O}_{t+1:T} | \mathbf{s}_{t+1}, \mathbf{s}_t, \mathbf{a}_t) p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) p(\mathcal{O}_t | \mathbf{s}_t, \mathbf{a}_t) d\mathbf{s}_{t+1} \quad (12.7)$$

$$= \int p(\mathcal{O}_{t+1:T} | \mathbf{s}_{t+1}) \underbrace{p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t)}_{\text{known}} \underbrace{p(\mathcal{O}_t | \mathbf{s}_t, \mathbf{a}_t)}_{\text{known}} d\mathbf{s}_{t+1} \quad (12.8)$$

$$= p(\mathcal{O}_t | \mathbf{s}_t, \mathbf{a}_t) \int p(\mathcal{O}_{t+1:T} | \mathbf{s}_{t+1}) p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) d\mathbf{s}_{t+1} \quad (12.9)$$

$$\Rightarrow \beta_t(\mathbf{s}_t, \mathbf{a}_t) = p(\mathcal{O}_t | \mathbf{s}_t, \mathbf{a}_t) \mathbb{E}_{\mathbf{s}_{t+1} \sim p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t)} [\beta_{t+1}(\mathbf{s}_{t+1})] \quad (12.10)$$

$$p(\mathcal{O}_{t+1:T} | \mathbf{s}_{t+1}) = \int \underbrace{p(\mathcal{O}_{t+1:T} | \mathbf{s}_{t+1}, \mathbf{a}_{t+1})}_{\text{backward message } \beta_{t+1}(\mathbf{s}_{t+1}, \mathbf{a}_{t+1})} \underbrace{p(\mathbf{a}_{t+1} | \mathbf{s}_{t+1})}_{\text{action prior}} d\mathbf{a}_{t+1} \quad (12.11)$$

$$\Rightarrow \beta_t(\mathbf{s}_t) = \mathbb{E}_{\mathbf{a}_{t+1} \sim p(\mathbf{a}_t | \mathbf{s}_t)} [\beta_t(\mathbf{s}_t, \mathbf{a}_t)] \quad (\text{assuming uniform action prior } p(\mathbf{a}_t | \mathbf{s}_t)) \quad (12.12)$$

Recursive algorithm:

$$\beta_T(\mathbf{s}_T, \mathbf{a}_T) = p(\mathcal{O}_T | \mathbf{s}_T, \mathbf{a}_T) = \exp(r(\mathbf{s}_T, \mathbf{a}_T)) \quad (12.13)$$

$$\text{for } t = T - 1 \rightarrow 1 : \quad (12.14)$$

$$\beta_t(\mathbf{s}_t, \mathbf{a}_t) = p(\mathcal{O}_t | \mathbf{s}_t, \mathbf{a}_t) \mathbb{E}_{\mathbf{s}_{t+1} \sim p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t)} [\beta_{t+1}(\mathbf{s}_{t+1})] \quad (12.15)$$

$$\beta_t(\mathbf{s}_t) = \mathbb{E}_{\mathbf{a}_t \sim p(\mathbf{a}_t | \mathbf{s}_t)} [\beta_t(\mathbf{s}_t, \mathbf{a}_t)] \quad (12.16)$$

### Further examination:

$$\text{let } V_t(\mathbf{s}_t) = \log \beta_t(\mathbf{s}_t)$$

$$\text{let } Q_t(\mathbf{s}_t, \mathbf{a}_t) = \log \beta_t(\mathbf{s}_t, \mathbf{a}_t)$$

$$V_t(\mathbf{s}_t) = \log \int \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t)) d\mathbf{a}_t$$

$$V_t(\mathbf{s}_t) \rightarrow \max_{\mathbf{a}_t} Q_t(\mathbf{s}_t, \mathbf{a}_t) \text{ as } Q_t(\mathbf{s}_t, \mathbf{a}_t) \text{ gets bigger!} \Rightarrow \text{"soft max"}$$

$$Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \log \mathbb{E}[\exp V_{t+1}(\mathbf{s}_{t+1})]$$

$$Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + V_{t+1}(\mathbf{s}_{t+1}) \quad \text{in case of deterministic transition}$$

The above looks a lot like Bellman's equation  $\Rightarrow \log \beta_t$  is "Q-function-like"

**NOTE:** Value functions are backward messages.

### 12.2.2 The Action Prior

Re-examine the action prior when computing the backward messages. Before, we assume it was uniform (as a constant to be ignored). If it's not uniform:

$$p(\mathcal{O}_{t+1:T} | \mathbf{s}_{t+1}) = \int \beta_{t+1}(\mathbf{s}_{t+1}, \mathbf{a}_{t+1}) p(\mathbf{a}_{t+1} | \mathbf{s}_{t+1}) d\mathbf{a}_{t+1} = \beta_{t+1}(\mathbf{s}_{t+1}) \quad (12.17)$$

$$\Rightarrow V(\mathbf{s}_t) = \log \int \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t) + \log p(\mathbf{a}_t | \mathbf{s}_t)) d\mathbf{a}_t = \log \beta_t(\mathbf{s}_t) \quad (12.18)$$

$$Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \log \mathbb{E}[\exp V_{t+1}(\mathbf{s}_{t+1})] \quad (\text{before}) \quad (12.19)$$

$$\tilde{Q}_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \log p(\mathbf{a}_t | \mathbf{s}_t) + \log \mathbb{E}[\exp V_{t+1}(\mathbf{s}_{t+1})] \quad (\text{modified}) \quad (12.20)$$

$$\Rightarrow V(\mathbf{s}_t) = \log \int \exp(\tilde{Q}_t(\mathbf{s}_t, \mathbf{a}_t)) d\mathbf{a}_t \quad (12.21)$$

Thus, a simple modification to the reward will take account of the non-uniform action prior.

$\Rightarrow$  we can assume uniform action prior without loss of generality.

### 12.2.3 Policy Computation

The policy  $p(\mathbf{a}_t | \mathbf{s}_t, \mathcal{O}_{1:T})$  is the current action prob. given the current state  $\mathbf{s}_t$  that the whole trajectory is optimal.

Given:

$p(\mathcal{O}_t   \mathbf{s}_t, \mathbf{a}_t) \propto \exp(r(\mathbf{s}_t, \mathbf{a}_t))$	– <b>prob.</b> of current optimality given state and action
$p(\mathbf{s}_{t+1}   \mathbf{s}_t, \mathbf{a}_t)$	– transition <b>prob.</b>
$\beta_t(\mathbf{s}_t, \mathbf{a}_t) = p(\mathcal{O}_{t:T}   \mathbf{s}_t, \mathbf{a}_t)$	– backward messages
$\beta_t(\mathbf{s}_t) = p(\mathcal{O}_{t:T}   \mathbf{s}_t)$	– backward state messages

Formulation:

$$p(\mathbf{a}_t | \mathbf{s}_t, \mathcal{O}_{1:T}) = \pi(\mathbf{a}_t | \mathbf{s}_t) = p(\mathbf{a}_t | \mathbf{s}_t, \mathcal{O}_{t:T}) \quad (12.22)$$

$$= \frac{p(\mathbf{a}_t, \mathbf{s}_t | \mathcal{O}_{t:T})}{p(\mathbf{s}_t | \mathcal{O}_{t:T})} \quad (12.23)$$

$$= \frac{p(\mathcal{O}_{t:T} | \mathbf{a}_t, \mathbf{s}_t) p(\mathbf{a}_t, \mathbf{s}_t) / p(\mathcal{O}_{t:T})}{p(\mathcal{O}_{t:T} | \mathbf{s}_t) p(\mathbf{s}_t) / p(\mathcal{O}_{t:T})} \quad (\text{Bayes rule}) \quad (12.24)$$

$$= \frac{p(\mathcal{O}_{t:T} | \mathbf{a}_t, \mathbf{s}_t)}{p(\mathcal{O}_{t:T} | \mathbf{s}_t)} \frac{p(\mathbf{a}_t, \mathbf{s}_t)}{p(\mathbf{s}_t)} = \frac{\beta_t(\mathbf{s}_t, \mathbf{a}_t)}{\beta_t(\mathbf{s}_t)} p(\mathbf{a}_t | \mathbf{s}_t) \quad (12.25)$$

$$\Rightarrow \pi(\mathbf{a}_t | \mathbf{s}_t) = \frac{\beta_t(\mathbf{s}_t, \mathbf{a}_t)}{\beta_t(\mathbf{s}_t)} \quad (\text{assume uniform action prior } p(\mathbf{a}_t | \mathbf{s}_t) = \text{const}) \quad (12.26)$$

Recursive algorithm:

$$\text{for } t = T - 1 \rightarrow 1 : \quad (12.27)$$

$$Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \log \mathbb{E} [\exp(V_{t+1}(\mathbf{s}_{t+1}))] \quad (12.28)$$

$$V_t(\mathbf{s}_t) = \log \int \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t)) d\mathbf{a}_t \quad (12.29)$$

Policy computation with value functions:

$$\pi(\mathbf{a}_t | \mathbf{s}_t) = \frac{\beta_t(\mathbf{s}_t, \mathbf{a}_t)}{\beta_t(\mathbf{s}_t)} \quad \text{with} \quad \begin{cases} V_t(\mathbf{s}_t) = \log \beta_t(\mathbf{s}_t) \\ Q_t(\mathbf{s}_t, \mathbf{a}_t) = \log \beta_t(\mathbf{s}_t, \mathbf{a}_t) \end{cases} \quad (12.30)$$

$$\Rightarrow \pi(\mathbf{a}_t | \mathbf{s}_t) = \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t) - V_t(\mathbf{s}_t)) = \exp(A_t(\mathbf{s}_t, \mathbf{a}_t)) \quad (12.31)$$

$\Rightarrow$  Soft advantage function with temperature:

$$\pi(\mathbf{a}_t | \mathbf{s}_t) = \exp\left(\frac{1}{\alpha} A_t(\mathbf{s}_t, \mathbf{a}_t)\right) \quad \begin{cases} \alpha \rightarrow 0 : \text{more deterministic} \\ \alpha \rightarrow 1 : \text{classical inference framework} \end{cases} \quad (12.32)$$

#### 12.2.4 Forward Messages Computation

The forward messages  $\alpha_t(\mathbf{s}_t) = p(\mathbf{s}_t | \mathcal{O}_{1:t-1})$  is the **prob.** of the state  $\mathbf{s}_t$  given that all previous trajectory steps are so far optimal.

Given:

$$\begin{aligned}
 p(\mathcal{O}_t | \mathbf{s}_t, \mathbf{a}_t) &\propto \exp(r(\mathbf{s}_t, \mathbf{a}_t)) && - \text{prob. of current optimality given state and action} \\
 p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) & && - \text{transition prob.} \\
 \alpha(\mathbf{s}_1) = p(\mathbf{s}_1) & && - \text{usually known}
 \end{aligned}$$

Formulation:

$$\alpha(\mathbf{s}_t) = p(\mathbf{s}_t | \mathcal{O}_{1:t-1}) \quad (12.33)$$

$$= \int p(\mathbf{s}_t, \mathbf{s}_{t-1}, \mathbf{a}_{t-1} | \mathcal{O}_{1:t-1}) d\mathbf{s}_{t-1} d\mathbf{a}_{t-1} \quad (12.34)$$

$$= \int p(\mathbf{s}_t | \mathbf{s}_{t-1}, \mathbf{a}_{t-1}, \mathcal{O}_{1:t-1}) p(\mathbf{a}_{t-1} | \mathbf{s}_{t-1}, \mathcal{O}_{1:t-1}) p(\mathbf{s}_{t-1} | \mathcal{O}_{1:t-1}) d\mathbf{s}_{t-1} d\mathbf{a}_{t-1} \quad (12.35)$$

$$= \underbrace{\int p(\mathbf{s}_t | \mathbf{s}_{t-1}, \mathbf{a}_{t-1})}_{\text{given}} p(\mathbf{a}_{t-1} | \mathbf{s}_{t-1}, \mathcal{O}_{t-1}) p(\mathbf{s}_{t-1} | \mathcal{O}_{1:t-1}) d\mathbf{s}_{t-1} d\mathbf{a}_{t-1} \quad (12.36)$$

$$p(\mathbf{a}_{t-1} | \mathbf{s}_{t-1}, \mathcal{O}_{t-1}) p(\mathbf{s}_{t-1} | \mathcal{O}_{1:t-1}) = \frac{p(\mathcal{O}_{t-1} | \mathbf{s}_{t-1}, \mathbf{a}_{t-1}) p(\mathbf{a}_{t-1} | \mathbf{s}_{t-1})}{p(\mathcal{O}_{t-1} | \mathbf{s}_{t-1})} \frac{p(\mathcal{O}_{t-1} | \mathbf{s}_{t-1}) p(\mathbf{s}_{t-1} | \mathcal{O}_{1:t-2})}{p(\mathcal{O}_{t-1} | \mathcal{O}_{1:t-2})} \quad (12.37)$$

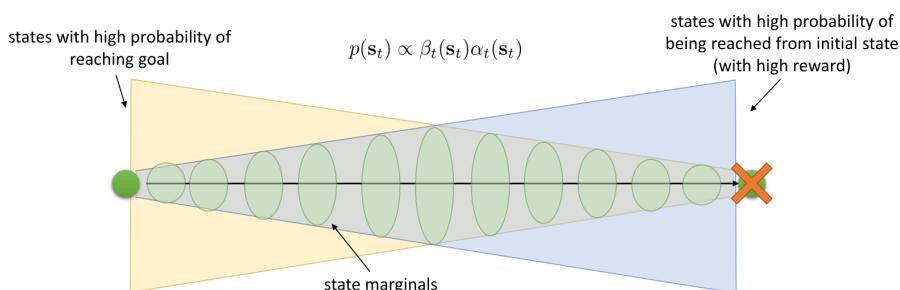

$$= \underbrace{p(\mathcal{O}_{t-1} | \mathbf{s}_{t-1}, \mathbf{a}_{t-1})}_{\text{given}} \underbrace{p(\mathbf{a}_{t-1} | \mathbf{s}_{t-1})}_{\text{action prior}} \frac{\overbrace{p(\mathbf{s}_{t-1} | \mathcal{O}_{1:t-2})}^{\alpha_{t-1}(\mathbf{s}_{t-1})}}{\overbrace{p(\mathcal{O}_{t-1} | \mathcal{O}_{1:t-2})}^{\alpha_{t-1}(\mathcal{O}_{1:t-2})}} \quad (12.38)$$

The state marginal:

$$p(\mathbf{s}_t | \mathcal{O}_{1:T}) = \frac{p(\mathbf{s}_t, \mathcal{O}_{1:T})}{p(\mathcal{O}_{1:T})} = \frac{\overbrace{p(\mathcal{O}_{t:T} | \mathbf{s}_t)}^{\beta_t(\mathbf{s}_t)} p(\mathbf{s}_t, \mathcal{O}_{1:t-1})}{p(\mathcal{O}_{1:T})} \quad (12.39)$$

$$\propto \beta_t(\mathbf{s}_t) \underbrace{p(\mathbf{s}_t | \mathcal{O}_{1:t-1})}_{\alpha_t(\mathbf{s}_t)} p(\mathcal{O}_{1:t-1}) \propto \beta_t(\mathbf{s}_t) \alpha_t(\mathbf{s}_t) \quad (12.40)$$

### 12.2.5 Forward / Backward Message Intersection

**Figure 12.1:** The intersection of backward and forward messages as state marginal ([UC Berkeley](#)).

## 12.3 Control as Variational Inference

### 12.3.1 Optimism Problem

The problem is due to the fact that given that you obtained high reward, the transition probability changes  $p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t, \mathcal{O}_{1:T}) \neq p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t)$ .

$$Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \underbrace{\log \mathbb{E} [\exp(V_{t+1}(\mathbf{s}_{t+1}))]}_{\text{"optimistic" transition}} \quad (12.41)$$

Unlike in classic MDP, the log of expectation of exp value function is overly optimistic, in the sense that a single large reward will overwhelm other values, while the average reward in expectation is low.

**Problem:** given that you obtained high reward, what was your action probability, *given that your transition probability did not change?*

**Idea:** find a distribution  $q(\mathbf{s}_{1:T}, \mathbf{a}_{1:T}) \approx p(\mathbf{s}_{1:T}, \mathbf{a}_{1:T}|\mathcal{O}_{1:T})$  but has dynamics  $p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t)$

### 12.3.2 Control via Variational Inference

- Let  $\mathbf{x} = \mathcal{O}_{1:T}$  and  $z = (\mathbf{s}_{1:T}, \mathbf{a}_{1:T})$   
 $\Rightarrow$  find  $q(z) \approx p(z|\mathbf{x})$
- Let  $q(z) = q(\mathbf{s}_{1:T}, \mathbf{a}_{1:T}) = p(\mathbf{s}_1) \prod_t p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t) q(\mathbf{a}_t|\mathbf{s}_t)$

The variational lower bound:  $\log p(\mathbf{x}) \geq \mathbb{E}_{z \sim q(z)} [\log p(\mathbf{x}, z) - \log q(z)]$  (AI notes)

$$\begin{aligned} \Rightarrow \log p(\mathcal{O}_{1:T}) &\geq \mathbb{E}_{(\mathbf{s}_{1:T}, \mathbf{a}_{1:T}) \sim q} \left[ \log p(\mathbf{s}_1) + \sum_{t=1}^T \log p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t) + \sum_{t=1}^T \log p(\mathcal{O}_t|\mathbf{s}_t, \mathbf{a}_t) \right. \\ &\quad \left. - \log p(\mathbf{s}_1) - \sum_{t=1}^T \log p(\mathbf{s}_{t+1}|\mathbf{s}_t, \mathbf{a}_t) - \sum_{t=1}^T \log q(\mathbf{a}_t|\mathbf{s}_t) \right] \\ &= \mathbb{E}_{(\mathbf{s}_{1:T}, \mathbf{a}_{1:T}) \sim q} \left[ \sum_t r(\mathbf{s}_t, \mathbf{a}_t) - \log q(\mathbf{a}_t|\mathbf{s}_t) \right] \\ &= \sum_t \mathbb{E}_{(\mathbf{s}_t, \mathbf{a}_t) \sim q} [r(\mathbf{s}_t, \mathbf{a}_t) + \mathcal{H}(q(\mathbf{a}_t|\mathbf{s}_t))] \end{aligned}$$

$\Rightarrow$  This objective is the RL objective, plus the action entropy. The additional action entropy term will give us more sub-optimal actions.

#### Optimization with dynamic programming:

- Base case: solve for the last time step  $q(\mathbf{a}_T|\mathbf{s}_T)$

$$\begin{aligned} q(\mathbf{a}_T|\mathbf{s}_T) &= \arg \max \mathbb{E}_{\mathbf{s}_T \sim q(\mathbf{s}_T)} [\mathbb{E}_{\mathbf{a}_T \sim q(\mathbf{a}_T|\mathbf{s}_T)} [r(\mathbf{s}_T, \mathbf{a}_T)] + \mathcal{H}(q(\mathbf{a}_T|\mathbf{s}_T))] \\ &= \arg \max \mathbb{E}_{\mathbf{s}_T \sim q(\mathbf{s}_T)} [\mathbb{E}_{\mathbf{a}_T \sim q(\mathbf{a}_T|\mathbf{s}_T)} [r(\mathbf{s}_T, \mathbf{a}_T) - \log q(\mathbf{a}_T|\mathbf{s}_T)]] \end{aligned}$$

Taking the derivative will result in:  $q(\mathbf{a}_T | \mathbf{s}_T) \propto \exp(r(\mathbf{s}_T, \mathbf{a}_T))$

$$q(\mathbf{a}_T | \mathbf{s}_T) = \frac{\exp(r(\mathbf{s}_T, \mathbf{a}_T))}{\int \exp(r(\mathbf{s}_T, \mathbf{a})) d\mathbf{a}} = \exp(Q(\mathbf{s}_T, \mathbf{a}_T) - V(\mathbf{s}_T)) \quad (12.42)$$

$$V(\mathbf{s}_T) = \log \int \exp(Q(\mathbf{s}_T, \mathbf{a}_T)) d\mathbf{a}_T \quad (12.43)$$

$$\Rightarrow \mathbb{E}_{\mathbf{s}_T \sim q(\mathbf{s}_T)} [\mathbb{E}_{\mathbf{a}_T \sim q(\mathbf{a}_T | \mathbf{s}_T)} [r(\mathbf{s}_T, \mathbf{a}_T) - \log q(\mathbf{a}_T | \mathbf{s}_T)]] = \mathbb{E}_{\mathbf{s}_T \sim q(\mathbf{s}_T)} [\mathbb{E}_{\mathbf{a}_T \sim q(\mathbf{a}_T | \mathbf{s}_T)} [V(\mathbf{s}_T)]] \quad (12.44)$$

- At any time step:

$$Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \mathbb{E}[V_{t+1}(\mathbf{s}_{t+1})] \quad (\text{regular Bellman backup - not optimistic})$$

$$\begin{aligned} q(\mathbf{a}_t | \mathbf{s}_t) &= \arg \max \mathbb{E}_{\mathbf{s}_t \sim q(\mathbf{s}_t)} [\mathbb{E}_{\mathbf{a}_t \sim q(\mathbf{a}_t | \mathbf{s}_t)} [r(\mathbf{s}_t, \mathbf{a}_t) + \mathbb{E}_{\mathbf{s}_{t+1} \sim p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t)} [V(\mathbf{s}_{t+1})]] + \mathcal{H}(q(\mathbf{a}_t | \mathbf{s}_t))] \\ &= \arg \max \mathbb{E}_{\mathbf{s}_t \sim q(\mathbf{s}_t)} [\mathbb{E}_{\mathbf{a}_t \sim q(\mathbf{a}_t | \mathbf{s}_t)} [Q(\mathbf{s}_t, \mathbf{a}_t)] + \mathcal{H}(q(\mathbf{a}_t | \mathbf{s}_t))] \\ &= \arg \max \mathbb{E}_{\mathbf{s}_t \sim q(\mathbf{s}_t)} [\mathbb{E}_{\mathbf{a}_t \sim q(\mathbf{a}_t | \mathbf{s}_t)} [Q(\mathbf{s}_t, \mathbf{a}_t) - \log q(\mathbf{a}_t | \mathbf{s}_t)]] \end{aligned}$$

optimized when:  $q(\mathbf{a}_t | \mathbf{s}_t) \propto \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t))$

$$V_t(\mathbf{s}_t) = \log \int \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t)) d\mathbf{a}_t$$

$$q(\mathbf{a}_t | \mathbf{s}_t) = \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t) - V_t(\mathbf{s}_t))$$

Now we have a dynamic programming [algor.](#) for backward pass, [a.k.a.](#) *soft* value iteration [algor.](#), which is similar to value iteration [algor.](#):

for  $t = T - 1 \rightarrow 1$ :

$$Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \mathbb{E}[V_{t+1}(\mathbf{s}_{t+1})]$$

$$V_t(\mathbf{s}_t) = \log \int \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t)) d\mathbf{a}_t$$

Value iteration [algor.](#) (Sec. 6.3)

*Soft* value iteration [algor.](#) [Lev18]

↳ 1. set  $Q(\mathbf{s}, \mathbf{a}) \leftarrow r(\mathbf{s}, \mathbf{a}) + \gamma \mathbb{E}[V(\mathbf{s}')]$   
 ↳ 2. set  $V(\mathbf{s}) \leftarrow \max_a Q(\mathbf{s}, \mathbf{a})$

↳ 1. set  $Q(\mathbf{s}, \mathbf{a}) \leftarrow r(\mathbf{s}, \mathbf{a}) + \gamma \mathbb{E}[V(\mathbf{s}')]$   
 ↳ 2. set  $V(\mathbf{s}) \leftarrow \text{soft max}_a Q(\mathbf{s}, \mathbf{a})$

Variants:

- Discounted SOC:  $Q_t(\mathbf{s}_t, \mathbf{a}_t) = r(\mathbf{s}_t, \mathbf{a}_t) + \gamma \mathbb{E}[V_{t+1}(\mathbf{s}_{t+1})]$
- Explicit temperature:  $V_t(\mathbf{s}_t) = \alpha \log \int \exp(\frac{1}{\alpha} Q_t(\mathbf{s}_t, \mathbf{a}_t)) d\mathbf{a}_t$

## 12.4 RL Algorithms as Inference

Benefits of soft optimality

- Improve exploration and prevent entropy collapse
- Easier to specialize (finetune) policies for more specific tasks

- Principled approach to break ties
- Better robustness (due to wider coverage of states)
- Can reduce to hard optimality as reward magnitude increases
- Good model for modeling human behavior

### 12.4.1 Soft Q-Learning

Q-Learning with Soft Optimality simply changes to the soft max:

- Standard Q-learning (Sec. 6.9):

$$\begin{aligned}\phi &\leftarrow \phi + \alpha \nabla_\phi Q_\phi(\mathbf{s}, \mathbf{a}) (r(\mathbf{s}, \mathbf{a}) + \gamma V(\mathbf{s}') - Q_\phi(\mathbf{s}, \mathbf{a})) \\ V(\mathbf{s}') &= \max_{\mathbf{a}'} Q_\phi(\mathbf{s}', \mathbf{a}') \quad (\text{target value})\end{aligned}$$

- Soft Q-learning:

$$\begin{aligned}\phi &\leftarrow \phi + \alpha \nabla_\phi Q_\phi(\mathbf{s}, \mathbf{a}) (r(\mathbf{s}, \mathbf{a}) + \gamma V(\mathbf{s}') - Q_\phi(\mathbf{s}, \mathbf{a})) \\ V(\mathbf{s}') &= \text{soft max}_{\mathbf{a}'} Q_\phi(\mathbf{s}', \mathbf{a}') = \log \int \exp(Q_\phi(\mathbf{s}', \mathbf{a}')) d\mathbf{a}' \quad (\text{target value}) \\ \pi(\mathbf{a}|\mathbf{s}) &= \exp(Q_\phi(\mathbf{s}, \mathbf{a}) - V(\mathbf{s})) = \exp(A_\phi(\mathbf{s}, \mathbf{a}))\end{aligned}$$

- 1. Take some action  $\mathbf{a}_i$  and observe  $(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)$ , add it to  $\mathcal{R}$   
 2. Sample mini-batch  $\{(\mathbf{s}_j, \mathbf{a}_j, \mathbf{s}'_j, r_j)\}$  from  $\mathcal{R}$  uniformly  
 3. Compute  $y_j = r_j + \gamma \text{soft max}_{\mathbf{a}'_j} Q_{\phi'}(\mathbf{s}'_j, \mathbf{a}'_j)$  using target network  $Q_{\phi'}$   
 4.  $\phi \leftarrow \phi - \alpha \sum_j \frac{dQ_\phi}{d\phi}(\mathbf{s}_j, \mathbf{a}_j) (Q_\phi(\mathbf{s}_j, \mathbf{a}_j) - y_j)$   
 5. Update  $\phi'$ : copy  $\phi$  every  $N$  steps, or Polyak average  $\phi' \leftarrow \tau\phi' + (1 - \tau)\phi$

### 12.4.2 Entropy Regularized Policy Gradient

Policy gradient with soft optimality:

$$\pi(\mathbf{a}|\mathbf{s}) = \exp(Q_\phi(\mathbf{s}, \mathbf{a}) - V(\mathbf{s})) \text{ optimizes } J(\theta) = \sum_t \mathbb{E}_{\pi(\mathbf{s}_t, \mathbf{a}_t)}[r(\mathbf{s}_t, \mathbf{a}_t)] + \mathbb{E}_{\pi(\mathbf{s}_t)}[\mathcal{H}(\pi(\mathbf{a}_t|\mathbf{s}_t))]$$

Intuition:

$$\begin{aligned}\pi(\mathbf{a}|\mathbf{s}) &\propto \exp(Q_\phi(\mathbf{s}, \mathbf{a})) \text{ when } \pi \text{ minimizes } D_{KL}\left(\pi(\mathbf{a}|\mathbf{s}) \middle\| \frac{1}{Z} \exp(Q(\mathbf{s}, \mathbf{a}))\right) \\ D_{KL}\left(\pi(\mathbf{a}|\mathbf{s}) \middle\| \frac{1}{Z} \exp(Q(\mathbf{s}, \mathbf{a}))\right) &= \mathbb{E}_{\pi(\mathbf{a}|\mathbf{s})}[Q(\mathbf{s}, \mathbf{a})] - \mathcal{H}(\pi)\end{aligned}$$

### 12.4.3 Soft Policy Gradient vs Soft Q-Learning

Soft policy gradient derivation:

$$J(\theta) = \sum_t \mathbb{E}_{\pi(\mathbf{s}_t, \mathbf{a}_t)}[r(\mathbf{s}_t, \mathbf{a}_t)] + \mathbb{E}_{\pi(\mathbf{s}_t)}[\mathcal{H}(\pi(\mathbf{a}_t|\mathbf{s}_t))] \quad (12.45)$$

$$= \sum_t \mathbb{E}_{\pi(\mathbf{s}_t, \mathbf{a}_t)}[r(\mathbf{s}_t, \mathbf{a}_t) - \log \pi(\mathbf{a}_t|\mathbf{s}_t)] \quad (12.46)$$

$$\nabla_{\theta} J = \nabla_{\theta} \left[ \sum_t \mathbb{E}_{\pi(\mathbf{s}_t, \mathbf{a}_t)}[r(\mathbf{s}_t, \mathbf{a}_t) - \log \pi(\mathbf{a}_t|\mathbf{s}_t)] \right] \quad (12.47)$$

$$\approx \frac{1}{N} \sum_i \sum_t \nabla_{\theta} \log \pi(\mathbf{a}_t|\mathbf{s}_t) \left( r(\mathbf{s}_t, \mathbf{a}_t) + \underbrace{\left( \sum_{t'=t+1}^T r(\mathbf{s}_{t'}, \mathbf{a}_{t'}) - \log \pi(\mathbf{a}_{t'}|\mathbf{s}_{t'}) \right)}_{\approx Q(\mathbf{s}_{t+1}, \mathbf{a}_{t+1})} - \log \pi(\mathbf{a}_t|\mathbf{s}_t) - 1 \right) \quad (12.48)$$

We can ignore the  $-1$  in the end (baseline).

Recall  $\pi(\mathbf{a}_t|\mathbf{s}_t) = \exp(Q_t(\mathbf{s}_t, \mathbf{a}_t) - V_t(\mathbf{s}_t))$  (Subsec. 12.2.3):

$$\nabla_{\theta} J(\theta) \approx \frac{1}{N} \sum_i \sum_t (\nabla_{\theta} Q_t(\mathbf{s}_t, \mathbf{a}_t) - \nabla_{\theta} V_t(\mathbf{s}_t)) (r(\mathbf{s}_t, \mathbf{a}_t) + Q(\mathbf{s}_{t+1}, \mathbf{a}_{t+1}) - Q_t(\mathbf{s}_t, \mathbf{a}_t) + \cancel{V(\mathbf{s}_t)}) \quad (12.49)$$

Because of the baseline properties, any state dependent baseline can be removed, thus, we can ignore the  $V(\mathbf{s}_t)$ .

Soft Q-learning (gradient descent, instead of gradient ascent in policy gradient):

$$\nabla_{\theta} J(\theta) \approx -\frac{1}{N} \sum_i \sum_t \nabla_{\theta} Q_t(\mathbf{s}_t, \mathbf{a}_t) (r(\mathbf{s}_t, \mathbf{a}_t) + \text{soft max}_{\mathbf{a}_{t+1}} Q(\mathbf{s}_{t+1}, \mathbf{a}_{t+1}) - Q_t(\mathbf{s}_t, \mathbf{a}_t)) \quad (12.50)$$

## 12.5 Soft Actor-Critic

Algorithm overview [HZA+18]:

1. Q-function update to evaluate current policy: this converges to  $Q^{\pi}$

$$Q(\mathbf{s}, \mathbf{a}) \leftarrow r(\mathbf{s}, \mathbf{a}) + \mathbb{E}_{\mathbf{s}' \sim p_{\mathbf{s}}, \mathbf{a}' \sim \pi}[Q(\mathbf{s}', \mathbf{a}') - \log \pi(\mathbf{a}'|\mathbf{s}')] \quad (12.51)$$

2. Update policy with gradient of information projection

$$\pi_{new} = \arg \min_{\pi'} D_{KL} \left( \pi'(\cdot|\mathbf{s}) \middle\| \frac{1}{Z} \exp Q^{\pi_{old}}(\mathbf{s}, \cdot) \right) \quad (12.52)$$

In practice, only take one gradient step on this objective

3. Interact with the world, collect more data

# 13 Offline Reinforcement Learning

One major challenge in **RL** is the ability to generalize to different tasks, unlike with supervised learning. E.g., supervised learning in Computer Vision (**CV**), a model can be trained on a large dataset (e.g., ImageNet), then retrained on a smaller dataset to adapt with a specific task. This is possible because it was proven that early layers manage to learn different feature representation. What **RL** differs from more conventional supervised learning are large diverse dataset, training procedure, how and when the data is collected, etc. Offline **RL** is one of proposed solution for **RL** generalization problem. This chapter examines how we can formulate **RL** similar to supervised learning.

## 13.1 Formulation

Offline **RL** is also known as batch **RL**, fully off-policy **RL**.

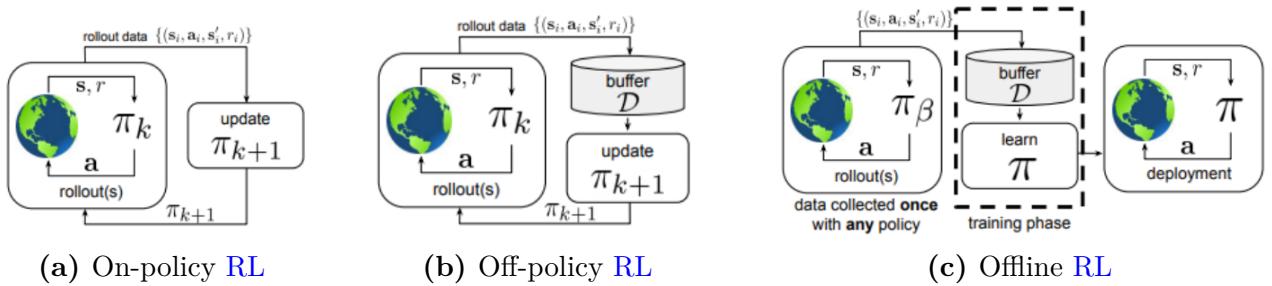

Figure 13.1: Different settings for **RL**.

Formal problem definition: Offline **RL**

$$\mathcal{D} = \{(s_i, a_i, s'_i, r_i)\} \quad - \text{dataset of transitions} \quad (13.1)$$

$$s \sim d^{\pi_\beta}(s) \quad (13.2)$$

$$a \sim \pi_\beta(a|s) \quad - \text{unknown policy} \quad (13.3)$$

$$s' \sim p(s'|s, a) \quad (13.4)$$

$$r \leftarrow r(s, a) \quad (13.5)$$

$$\max_{\pi} \sum_{t=0}^T \mathbb{E}_{s_t \sim d^{\pi_\beta}(s), a_t \sim \pi(a|s)} [\gamma^t r(s_t, a_t)] \quad - \text{RL objective} \quad (13.6)$$

- Off-policy evaluation (**OPE**): given  $\mathcal{D}$ , estimate  $J(\pi_\beta) = \mathbb{E}_{\pi_\beta} \left[ \sum_{t=1}^T r(s_t, a_t) \right]$

- Offline RL: given  $\mathcal{D}$ , learn the best possible policy  $\pi_\theta$ , which might not be the best possible policy for the MDP

We hope this is possible because: we expect the model can

- Find the "*good stuff*" in a dataset full of good and bad behaviors
- Generalization: good behavior in one place may suggest good behavior in another place
- "*Stitching*": parts of good behaviors can be recombined [SYY+20]

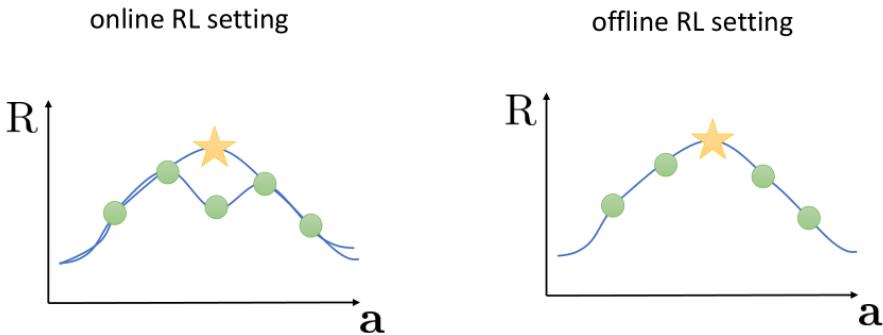

## 13.2 Challenges

- Little amount of online tuning has significantly more impact than offline training [KIP+18]
- Distribution shift

$$\begin{aligned} \theta \leftarrow \arg \max_{\theta} \mathbb{E}_{\mathbf{x} \sim p(\mathbf{x}), y \sim p(y|\mathbf{x})} [(f_{\theta}(\mathbf{x}) - y)^2] & \quad - \text{normal regression problem} \\ \mathbb{E}_{\mathbf{x}' \sim p(\mathbf{x})} [(f_{\theta}(\mathbf{x}') - y)^2] & \quad - \text{is low in expectation} \\ \mathbb{E}_{\mathbf{x}' \sim \bar{p}(\mathbf{x})} [(f_{\theta}(\mathbf{x}') - y)^2] & \quad - \text{is not, for general } \bar{p}(\mathbf{x}) \neq p(\mathbf{x}) \\ \mathbb{E}_{\mathbf{x}' \sim p(\mathbf{x})} [(f_{\theta}(\mathbf{x}') - y)^2] & \quad - \text{is } \textbf{NOT} \text{ low if } \mathbf{x}' \leftarrow \arg \max_{\mathbf{x}} f_{\theta}(\mathbf{x}) \end{aligned}$$

This is exactly what happens for value-based RL approaches, in which we decide the action based on maximizing the value function  $\Rightarrow$  Over-estimation of value function [KFS+19]

- Counterfactual queries: must account for out-of-distribution actions, ideally in a safe way, while still making use of generalization to come up with behaviors that are better than the best thing seen in the data [LKT+20]
- Issues with generalization are not corrected:

## 13.3 Classic Offline RL

If you want to use offline RL today, you probably would not use approaches in this section.

### 13.3.1 Batch RL via Importance Sampling

Batch RL is just an old name for offline RL (around 2000s). Using importance sampling, we can use samples from one policy to learn another one (Sec. 4.4)

$$\begin{aligned}
 & \max_{\pi} \sum_{t=0}^T \mathbb{E}_{\mathbf{s}_t \sim d^\pi(\mathbf{s}), \mathbf{a}_t \sim \pi(\mathbf{a}|\mathbf{s})} [\gamma^t r(\mathbf{s}_t, \mathbf{a}_t)] && - \text{RL objective} \\
 \nabla_{\theta} J(\theta) &= \mathbb{E}_{\tau \sim \pi_{\theta}(\tau)} \left[ \sum_{t=0}^T \nabla_{\theta} \gamma^t \log \pi_{\theta}(\mathbf{a}_t | \mathbf{s}_t) \hat{Q}(\mathbf{s}_t, \mathbf{a}_t) \right] && - \text{policy gradient} \\
 &\approx \frac{1}{N} \sum_{i=1}^N \sum_{t=0}^T \nabla_{\theta} \gamma^t \log \pi_{\theta}(\mathbf{a}_{t,i} | \mathbf{s}_{t,i}) \hat{Q}(\mathbf{s}_{t,i}, \mathbf{a}_{t,i}) && \text{requires sampling from } \pi_{\theta} \\
 \nabla_{\theta} J(\theta) &\approx \frac{1}{N} \sum_{i=1}^N \underbrace{\frac{\pi_{\theta}(\tau_i)}{\pi_{\beta}(\tau_i)}}_{\text{importance weight}} \sum_{t=0}^T \nabla_{\theta} \gamma^t \log \pi_{\theta}(\mathbf{a}_{t,i} | \mathbf{s}_{t,i}) \hat{Q}(\mathbf{s}_{t,i}, \mathbf{a}_{t,i}) && \text{use samples from } \pi_{\beta} \\
 \frac{\pi_{\theta}(\tau)}{\pi_{\beta}(\tau)} &= \frac{p(\mathbf{s}_1) \prod_t p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \pi_{\theta}(\mathbf{a}_t | \mathbf{s}_t)}{p(\mathbf{s}_1) \prod_t p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \pi_{\beta}(\mathbf{a}_t | \mathbf{s}_t)} && \text{exponential in } T \\
 \hat{Q}(\mathbf{s}_{t,i}, \mathbf{a}_{t,i}) &= \mathbb{E}_{\pi_{\theta}} \left[ \sum_{t'=t}^T \gamma^{t'-t} r_{t'} \right] \approx \sum_{t'=t}^T \gamma^{t'-t} r_{t',i} && \text{single sample estimate} \\
 \Rightarrow \nabla_{\theta} J(\theta) &\approx \frac{1}{N} \sum_{i=1}^N \sum_{t=0}^T \underbrace{\left( \prod_{t'=0}^{t-1} \frac{\pi_{\theta}(\mathbf{a}_{t',i} | \mathbf{s}_{t',i})}{\pi_{\beta}(\mathbf{a}_{t',i} | \mathbf{s}_{t',i})} \right)}_{\text{accounts for difference in prob. of landing in } \mathbf{s}_{t,i}, \\ \text{we have } \mathbf{s}_t \sim d^{\pi_{\beta}}(\mathbf{s}_t), \\ \text{but want } \mathbf{s}_t \sim d^{\pi_{\theta}}(\mathbf{s}_t)} \nabla_{\theta} \gamma^t \log \pi_{\theta}(\mathbf{a}_{t,i} | \mathbf{s}_{t,i}) \underbrace{\left( \prod_{t'=t}^T \frac{\pi_{\theta}(\mathbf{a}_{t',i} | \mathbf{s}_{t',i})}{\pi_{\beta}(\mathbf{a}_{t',i} | \mathbf{s}_{t',i})} \right)}_{\text{accounts for having incorrect } \hat{Q}(\mathbf{s}_{t,i}, \mathbf{a}_{t,i})} \hat{Q}(\mathbf{s}_{t,i}, \mathbf{a}_{t,i})
 \end{aligned}$$

[TODO: Ignore for now, too many complicated equations]

### 13.3.2 Batch RL via Linear Fitted Value Functions

Let's go back to the model-based RL setting with tabular linear fitted value functions. This method generally doesn't concern with distributional shift, maybe it was not such a big problem with linear models.

High level idea procedure:

1. Estimate the reward
2. Estimate the transitions
3. Recover the value function
4. Improve the policy

$\Phi$  – feature matrix, size  $|S| \times K$  (13.7)

$\Phi \mathbf{w}_r \approx r$  – reward model,  $\mathbf{w}_r \in \mathbb{R}^{K \times 1}$ ,  $r \in \mathbb{R}^{|S| \times 1}$  (13.8)

$\Rightarrow \mathbf{w}_r = (\Phi^T \Phi)^{-1} \Phi^T \vec{\mathbf{r}}$  – least square solution (assume knowing  $\vec{\mathbf{r}}$ ) (13.9)

$\Phi \mathbf{P}_\Phi \approx \mathbf{P}^\pi \Phi$  – transition model (13.10)

$\mathbf{P}^\pi \in \mathbb{R}^{|S| \times |S|}$  – real transition matrix (on states) (13.11)

$\mathbf{P}_\Phi \in \mathbb{R}^{K \times K}$  – estimated feature-space transition matrix (13.12)

$\Rightarrow \mathbf{P}_\Phi = (\Phi^T \Phi)^{-1} \Phi^T \mathbf{P}^\pi \Phi$  – least squares (13.13)

$\Rightarrow V^\pi \approx V_\Phi^\pi = \Phi \mathbf{w}_V$  – value functions (13.14)

We can find  $V^\pi$  in terms of  $\mathbf{P}^\pi$  and  $\mathbf{r}$ :

$$V^\pi = \mathbf{r} + \gamma \mathbf{P}^\pi V^\pi \quad (13.15)$$

$$\Rightarrow V^\pi = (\mathbf{I} - \gamma \mathbf{P}^\pi)^{-1} \mathbf{r} \quad (13.16)$$

Same derivation in feature space:

$$\mathbf{w}_V = (\mathbf{I} - \gamma \mathbf{P}_\Phi)^{-1} \mathbf{w}_r \quad (13.17)$$

$$= (\mathbf{I} - \gamma (\Phi^T \Phi)^{-1} \Phi^T \mathbf{P}^\pi \Phi)^{-1} (\Phi^T \Phi)^{-1} \Phi^T \vec{\mathbf{r}} \quad \text{– substitute in } \mathbf{w}_r \text{ and } \mathbf{P}_\Phi \quad (13.18)$$

$$\Rightarrow \mathbf{w}_V = (\Phi^T \Phi - \gamma \Phi^T \mathbf{P}^\pi \Phi)^{-1} \Phi^T \vec{\mathbf{r}} \quad \text{– LSTD} \quad (13.19)$$

The above equations are of Least-squares Temporal Difference (LSTD). However it requires us to know transition matrix  $\mathbf{P}^\pi$  and reward vector  $\vec{\mathbf{r}}$ . To get a model-free approach, we will use samples. We replace  $\mathbf{P}^\pi \Phi$  with the feature matrix of the next time step  $\Phi'$ :

$$\Phi'_i = \phi(\mathbf{s}'_i) \quad (13.20)$$

**LSTD Algorithm:** not going to work for offline RL, because the equation requires samples from  $\pi$  for  $\mathbf{P}^\pi$

- 1.  $\pi'(\mathbf{s}) \leftarrow \text{Greedy}(\Phi \mathbf{w}_V)$
- 2. estimate  $V^{\pi'}$

**Least-squares Policy Iteration (LSPI) Algorithm:** LSTDQ - LSTD for Q-functions.

- 1. compute  $\mathbf{w}_Q$  for  $\pi_k$
- 2.  $\pi_{k+1}(\mathbf{s}) = \arg \max_{\mathbf{a}} \phi(\mathbf{s}, \mathbf{a}) \mathbf{w}_Q$
- 3. set  $\Phi'_i = \phi(\mathbf{s}'_i, \pi_{k+1}(\mathbf{s}'_i))$

Now  $\Phi \in \mathbb{R}^{|S||A| \times K'}$ ,  $\mathbf{w}_Q = (\Phi^T \Phi - \gamma \Phi^T \Phi')^{-1} \Phi^T \vec{\mathbf{r}}$ ,  $\vec{\mathbf{r}}_i = r(\mathbf{s}_i, \mathbf{a}_i)$  [LP03]

# 14 Inverse Reinforcement Learning

Prior to this, we have been manually design the reward function, which defines the task. There are cases, the reward function is unavailable or difficult to specify. The idea behind inverse RL is to use human / expert's experience to *learn* the reward function, then use it for RL as a goal to optimize.

There is a difference between standard imitation learning and human imitation learning:

- Standard imitation learning:
  - copy the *actions* performed by the expert
  - no reasoning about outcomes of actions
- Human imitation learning:
  - copy the *intent* of the expert
  - might take very different actions!

## 14.1 Definition

Inverse RL vs. "forward" RL:

"Forward" RL	Inverse RL
given: states $s \in \mathcal{S}$ , actions $a \in \mathcal{A}$ (sometimes) transitions $p(s' s, a)$ reward function $r(s, a)$	given: states $s \in \mathcal{S}$ , actions $a \in \mathcal{A}$ (sometimes) transitions $p(s' s, a)$ samples $\{\tau_i\}$ sampled from $\pi^*(\tau)$
learn $\pi^*(a s)$	learn $r_\psi(s, a)$ ... and then use it to learn $\pi^*(a s)$

Choices for  $\psi$ :

- linear reward function:  $r_\psi(s, a) = \sum_i \psi_i f_i(s, a) = \psi^T \mathbf{f}(s, a)$
- neural net reward function:  $r_\psi(s, a)$

## 14.2 Feature matching IRL

- Linear reward function:  $r_\psi(\mathbf{s}, \mathbf{a}) = \sum_i \psi_i f_i(\mathbf{s}, \mathbf{a}) = \psi^T \mathbf{f}(\mathbf{s}, \mathbf{a})$
  - Let  $\pi^{r_\psi}$  be the optimal policy for  $r_\psi$ ,  $\pi^*$  be the unknown optimal policy
  - Pick  $\psi$  such that  $\mathbb{E}_{\pi^{r_\psi}}[\mathbf{f}(\mathbf{s}, \mathbf{a})] = \mathbb{E}_{\pi^*}[\mathbf{f}(\mathbf{s}, \mathbf{a})]$

Problem: still ambiguous

## Maximum Margin Principle:

$$\max_{\psi, m} m \quad \text{such that } \psi^T \mathbb{E}_{\pi^*}[\mathbf{f}(\mathbf{s}, \mathbf{a})] \geq \max_{\pi \in \Pi} \psi^T \mathbb{E}_\pi[\mathbf{f}(\mathbf{s}, \mathbf{a})] + m$$

$$\Leftrightarrow \min_{\psi} \frac{1}{2} \|\psi\|^2 \quad \text{such that } \psi^T \mathbb{E}_{\pi^*}[\mathbf{f}(\mathbf{s}, \mathbf{a})] \geq \max_{\pi \in \Pi} \psi^T \mathbb{E}_\pi[\mathbf{f}(\mathbf{s}, \mathbf{a})] + D(\pi, \pi^*) \quad (\text{SVM trick})$$

**Issues:** [AN04; RBZ06]

- Maximizing the margin is a bit arbitrary
  - No clear model of expert suboptimality (can add slack variables...)
  - Messy constrained optimization problem – not great for deep learning!

### 14.3 MaxEnt IRL Algorithm

Using the graphical model (Sec. 12.1), we approach the problem as maximum likelihood learning: learning the `params`.  $\psi$  to maximize the `prob.` of expert's trajectories given that they are (sub)optimal.

$$p(\mathcal{O}_t | \mathbf{s}_t, \mathbf{a}_t, \psi) = \exp(r_\psi(\mathbf{s}_t, \mathbf{a}_t)) \quad (14.1)$$

$$p(\tau | \mathcal{O}_{1:T}) = \frac{p(\tau, \mathcal{O}_{1:T})}{p(\mathcal{O}_{1:T})} \propto p(\cancel{\tau}) \exp\left(\sum_t r_\psi(\mathbf{s}_t, \mathbf{a}_t)\right) \quad (p(\tau) \text{ is independent of } \psi) \quad (14.2)$$

The Inverse Reinforcement Learning ([IRL](#))'s goal:

$$\psi = \arg \max_{\psi} \frac{1}{N} \sum_{i=1}^N \log p(\tau_i | \mathcal{O}_{1:T}, \psi) = \arg \max_{\psi} \frac{1}{N} \sum_{i=1}^N r_{\psi}(\tau_i) - \log Z = \arg \max_{\psi} \mathcal{L}(\psi) \quad (14.3)$$

The IRL partition function:

$$Z = \int p(\tau) \exp(r_\psi(\tau)) d\tau \quad (Z - \text{partition function}) \quad (14.4)$$

$$\nabla_{\psi} \mathcal{L} = \frac{1}{N} \sum_{i=1}^N \nabla_{\psi} r_{\psi}(\tau_i) - \underbrace{\frac{1}{Z} \int p(\tau) \exp(r_{\psi}(\tau)) \nabla_{\psi} r_{\psi}(\tau) d\tau}_{p(\tau | \mathcal{O}_{1:T}, \psi)} \quad (14.5)$$

$$= \mathbb{E}_{\tau \sim \pi^*(\tau)} [\nabla_\psi r_\psi(\tau_i)] - \mathbb{E}_{\tau \sim p(\tau | \mathcal{O}_{1:T}, \psi)} [\nabla_\psi r_\psi(\tau)] \quad (14.6)$$

expert samples      soft optimal policy

The gradient is the difference between the expectation of the derivative of trajectory's reward between the expert's and the one from rolling out the current policy.

Estimation of the 2nd term:

$$\mathbb{E}_{\tau \sim p(\tau | \mathcal{O}_{1:T}, \psi)} [\nabla_{\psi} r_{\psi}(\tau)] = \mathbb{E}_{\tau \sim p(\tau | \mathcal{O}_{1:T}, \psi)} \left[ \nabla_{\psi} \sum_{t=1}^T r_{\psi}(\mathbf{s}_t, \mathbf{a}_t) \right] \quad (14.7)$$

$$= \sum_{t=1}^T \mathbb{E}_{(\mathbf{s}_t, \mathbf{a}_t) \sim p(\mathbf{s}_t, \mathbf{a}_t | \mathcal{O}_{1:T}, \psi)} [\nabla_{\psi} r_{\psi}(\mathbf{s}_t, \mathbf{a}_t)] \quad (14.8)$$

$$p(\mathbf{s}_t, \mathbf{a}_t | \mathcal{O}_{1:T}, \psi) = \underbrace{p(\mathbf{a}_t | \mathbf{s}_t, \mathcal{O}_{1:T}, \psi)}_{\text{the policy}} \quad \underbrace{p(\mathbf{s}_t | \mathcal{O}_{1:T}, \psi)}_{\text{the state marginal prob.}} \quad (14.9)$$

$$p(\mathbf{a}_t | \mathbf{s}_t, \mathcal{O}_{1:T}, \psi) = \frac{\beta(\mathbf{s}_t, \mathbf{a}_t)}{\beta(\mathbf{s}_t)} \quad p(\mathbf{s}_t | \mathcal{O}_{1:T}, \psi) \propto \alpha(\mathbf{s}_t) \beta(\mathbf{s}_t) \quad (\text{Sec. 12.2})$$

$$\Rightarrow p(\mathbf{s}_t, \mathbf{a}_t | \mathcal{O}_{1:T}, \psi) \propto \beta(\mathbf{s}_t, \mathbf{a}_t) \alpha(\mathbf{s}_t) \quad \text{let } \mu_t(\mathbf{s}_t, \mathbf{a}_t) \propto \beta(\mathbf{s}_t, \mathbf{a}_t) \alpha(\mathbf{s}_t)$$

$$\Rightarrow \mathbb{E}_{\tau \sim p(\tau | \mathcal{O}_{1:T}, \psi)} [\nabla_{\psi} r_{\psi}(\tau)] = \sum_{t=1}^T \int \int \mu_t(\mathbf{s}_t, \mathbf{a}_t) \nabla_{\psi} r_{\psi}(\mathbf{s}_t, \mathbf{a}_t) d\mathbf{s}_t d\mathbf{a}_t = \sum_{t=1}^T \vec{\mu}_t \nabla_{\psi} \vec{r}_{\psi} \quad (14.10)$$

Maximum Entropy ([MaxEnt](#)) IRL Algorithm:

- 1. Given  $\psi$ , compute backward message  $\beta(\mathbf{s}_t, \mathbf{a}_t)$
- 2. Given  $\psi$ , compute forward message  $\alpha(\mathbf{s}_t)$
- 3. Compute  $\mu(\mathbf{s}_t, \mathbf{a}_t) \propto \beta(\mathbf{s}_t, \mathbf{a}_t) \alpha(\mathbf{s}_t)$
- 4. Evaluate  $\nabla_{\psi} \mathcal{L} = \frac{1}{N} \sum_{i=1}^N \sum_{t=1}^T \nabla_{\psi} r_{\psi}(\mathbf{s}_{i,t}, \mathbf{a}_{i,t}) - \sum_{t=1}^T \int \int \mu(\mathbf{s}_t, \mathbf{a}_t) \nabla_{\psi} r_{\psi}(\mathbf{s}_t, \mathbf{a}_t) d\mathbf{s}_t d\mathbf{a}_t$
- 5.  $\psi \leftarrow \psi + \eta \nabla_{\psi} \mathcal{L}$

**The name [MaxEnt](#):** when  $r_{\psi}(\mathbf{s}_t, \mathbf{a}_t) = \psi^T \mathbf{f}(\mathbf{s}_t, \mathbf{a}_t)$ , the procedure optimizes  $\max_{\psi} \mathcal{H}(\pi^{r_{\psi}})$  such that  $\mathbb{E}_{\pi^{r_{\psi}}}[\mathbf{f}] = \mathbb{E}_{\pi^*}[\mathbf{f}]$ . It is as random as possible while matching features. [[ZMB+08](#)]

## 14.4 Guided Cost Learning Algorithm

**Problems:** MaxEnt IRL so far requires:

- Solving for (soft) optimal policy in the inner loop
- Enumerating all state-action tuples for visitation frequency and gradient

Practical problem settings:

- Large and continuous state and action spaces
- States obtained via sampling only
- Unknown dynamics

**Idea:** learn  $p(\mathbf{a}_t | \mathbf{s}_t, \mathcal{O}_{1:T}, \psi)$  using any max entropy RL algor., then run that policy to sample trajectories  $\{\tau_j\}$

$$\nabla_\psi \mathcal{L} \approx \frac{1}{N} \sum_{i=1}^N \nabla_\psi r_\psi(\tau_i) - \frac{1}{M} \sum_{j=1}^M \nabla_\psi r_\psi(\tau_j) \quad (14.11)$$

If instead of expensively learning the policy, we just improve the policy (a little), we could use **importance sampling** to handle the biased estimator. [FLA16]

$$\nabla_\psi \mathcal{L} \approx \frac{1}{N} \sum_{i=1}^N \nabla_\psi r_\psi(\tau_i) - \frac{1}{\sum_j w_j} \sum_{j=1}^M w_j \nabla_\psi r_\psi(\tau_j) \quad (14.12)$$

$$w_j = \frac{p(\tau) \exp(r_\psi(\tau_j))}{\pi(\tau_j)} \quad (14.13)$$

$$= \frac{p(\mathbf{s}_1) \prod_t p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \exp(r_\psi(\mathbf{s}_t, \mathbf{a}_t))}{p(\mathbf{s}_1) \prod_t p(\mathbf{s}_{t+1} | \mathbf{s}_t, \mathbf{a}_t) \pi(\mathbf{a}_t | \mathbf{s}_t)} = \frac{\exp\left(\sum_t r_\psi(\mathbf{s}_t, \mathbf{a}_t)\right)}{\prod_t \pi(\mathbf{a}_t | \mathbf{s}_t)} \quad (14.14)$$

## 14.5 IRL and GANs

Similarity between IRL and Generative Adversarial Network (GAN):

IRL	GAN [GPAM+14]
Player 1: policy $\pi_\theta$	Player 1: the generator $p_\theta(\mathbf{x}   \mathbf{z})$
Player 2: reward function $r_\psi$	Player 2: the discriminator $p_\psi(\mathbf{z}   \mathbf{x})$
- The policy improves itself to make it <b>harder</b> to distinguish its samples and the expert demonstrations	- The generator improves itself to make it <b>harder</b> to distinguish its samples and the real images
- The reward model improves itself to make it <b>easier</b> to distinguish the expert demonstrations and the policy's samples (Eq. 14.6)	- The discriminator improves itself to make it <b>easier</b> to distinguish the real images and the generator's samples

### 14.5.1 IRL as a GAN

The optimal discriminator for GAN is:  $D^*(\mathbf{x}) = \frac{p^*(\mathbf{x})}{p_\theta(\mathbf{x}) + p^*(\mathbf{x})}$ . For IRL, optimal policy approaches  $\pi_\theta(\tau) \propto p(\tau) \exp(r_\psi(\tau))$ . Thus choosing parameterization for discriminator in the

following way can remove importance weights (they are subsumed into  $Z$ ) [FCA+16]

$$D_\psi(\tau) = \frac{p(\tau) \frac{1}{Z} \exp(r(\tau))}{p_\theta(\tau) + p(\tau) \frac{1}{Z} \exp(r(\tau))} = \frac{\cancel{p(\tau)} \frac{1}{Z} \exp(r(\tau))}{\cancel{p(\tau)} \prod_t \pi_\theta(\mathbf{a}_t | \mathbf{s}_t) + \cancel{p(\tau)} \frac{1}{Z} \exp(r(\tau))} \quad (14.15)$$

$$= \frac{\frac{1}{Z} \exp(r(\tau))}{\prod_t \pi_\theta(\mathbf{a}_t | \mathbf{s}_t) + \frac{1}{Z} \exp(r(\tau))} \quad (14.16)$$

$$\psi \leftarrow \arg \max_{\psi} \mathbb{E}_{\tau \sim p^*} [\log D_\psi(\tau)] + \mathbb{E}_{\tau \sim \pi_\theta} [\log(1 - D_\psi(\tau))] \quad (14.17)$$

#### 14.5.2 Generative adversarial imitation learning

We could also use regular discriminator ( $D_\psi(\tau)$  as standard binary classifier) [HE16].

+often simpler to set up optimization, fewer moving parts

-discriminator knows nothing at convergence

-generally cannot re-optimize the “reward”

#### 14.5.3 Generalization via IRL

We need to decouple the **goal** from the **dynamics!** [FLL17]

# 15 Transfer and Multi-Task Learning

If we've solved prior tasks, we might acquire useful knowledge for solving a new task. In [RL](#), knowledge is stored in:

- Q-function: tells us which actions or states are good
- Policy: tells us which actions are potentially useful. Some actions are never useful!
- Models: what are the laws of physics that govern the world?
- Features/hidden states: provide us with a good representation

## 15.1 Definitions

- *Transfer learning* is using experience from ***one set of tasks*** for faster learning and better performance on a ***new task*** in [RL](#).
- In [RL](#), task = [MDP](#)
- *Shot*: number of attempts in the target domain
  - 0-shot: just run the policy trained in the source domain
  - 1-shot: try the task once
  - few shot: try the task a few times

No single solution!

- Forward transfer: train on one task, transfer to a new task
  - Transferring visual representations & domain adaptation
  - Domain adaptation in reinforcement learning
  - Randomization
- Multi-task transfer: train on many tasks, transfer to a new task
  - Sharing representations and layers across tasks in multi-task learning
  - Contextual policies
  - Optimization challenges for multi-task learning
  - Algorithms
- Transferring models and value functions
  - Model-based RL as a mechanism for transfer
  - Successor features & representations

## 15.2 Forward Transfer

*Forward transfer:* train on one task, transfer to a new task.

- Transferring visual representations & domain adaptation
- Domain adaptation in reinforcement learning
- Randomization

Common challenges:

- Domain shift: representations learned in the source domain might not work well in the target domain
- Difference in the **MDP**: some things that are possible to do in the source domain are not possible to do in the target domain
- Finetuning issues: if pretraining & finetuning, the finetuning process may still need to explore, but optimal policy during finetuning may be deterministic!

### **15.2.1 Domain Adaptation**

**Invariance assumption:** everything that is **different** between domains is **irrelevant**.

**Idea:** force a representation layer (a layer) to be domain invariant.  $p(x)$  is different, exists some  $z = f(x)$  such that  $p(y|z) = p(y|x)$ , but  $p(z)$  is the same in both source and target domains. [TDH+20]

Invariance is not enough when the dynamics don't match. [EAC+20]

$$\begin{aligned}\tilde{r}(s, a) &= r(s, a) + \Delta r(s, a) \\ \Delta r(s_t, a_t, s_{t+1}) &= \log p_{target}(s_{t+1}|s_t, a_t) - \log p_{source}(s_{t+1}|s_t, a_t) \\ \Delta r(s_t, a_t, s_{t+1}) &= \log p(target|s_t, a_t, s_{t+1}) - \log p(target|s_t, a_t) \\ &\quad - \log p(source|s_t, a_t, s_{t+1}) - \log p(source|s_t, a_t)\end{aligned}$$

**Problems:**

- The above approach considers limits in the target domain that doesn't present in source domain.
- But it doesn't consider things that can happen in target domain but limited in source domain.

### 15.2.2 Finetuning

Challenges:

- RL tasks are generally much less diverse
  - Features are less general
  - Policies & value functions become overly specialized
- Optimal policies in fully observed MDPs are deterministic
  - Loss of exploration at convergence
  - Low-entropy policies adapt very slowly to new settings

Finetuning with maximum-entropy policies: act *as randomly as possible* while collecting high rewards. [HTA+17]

## 15.4 Multi-Task Transfer

**Definition:** train on many tasks, transfer to a new task.

- Sharing representations and layers across tasks in multi-task learning
- Contextual policies
- Optimization challenges for multi-task learning
- Algorithms

Multi-task [RL](#) corresponds to a single-task [RL](#) in a [joint MDP](#).

**Challenges:**

- **Gradient interference:** becoming better on one task can make you worse on another  
*Negative transfer* implies the transfer actually hurting the task’s performance.
- **Winner-take-all problem:** imagine one task starts getting good algorithm is likely to prioritize that task (to increase average expected reward) at the expense of others.

The two approaches is not really multi-task transfer. Not really fasten the learning speed of other tasks

### 15.4.1 Actor-Mimic

- Train multiple single-task policy, then use supervised learning to combine them into one single policy. [RCG+15]
- Analogous to guided policy search (Sec. 10.4), but for transfer learning. [LK13]

### 15.4.2 Policy Distillation

Divide and Conquer does has some transfer between central policy and local policies, but not much. [PBS15]

### 15.4.3 Contextual Policies

Can do (discern) multiple things in the same environment.

- Standard policy:  $\pi_\theta(\mathbf{a}|\mathbf{s})$
- Contextual policy:  $\pi_\theta(\mathbf{a}|\mathbf{s}, \omega)$
- Augmented state space:  $\tilde{\mathbf{s}} = \begin{bmatrix} \mathbf{s} \\ \omega \end{bmatrix} \quad \tilde{\mathcal{S}} = \mathcal{S} \times \Omega$

## 15.5 Transferring Models and Value Functions

### Assumption:

- the **dynamics** is the same in both domains
- but the **reward function** is different

E.g.:

- Autonomous car learns how to drive to a few destinations, and then has to navigate to a new one.
- A kitchen robot learns to cook many different recipes, and

### 15.5.1 Transferring Models

Due to distribution shift, zero-shot might not always work. Although the dynamics is the same, they could be in different contexts: things present in source domain might not be present in target domain, and vice versa.

Unless the samples in the source domain is broad enough that they covers target domain's.

### 15.5.2 Transferring Value Functions

Value functions couple dynamics, rewards, and policies, but in linearity.

$$Q^\pi(\mathbf{s}, \mathbf{a}) = \underbrace{r(\mathbf{s}, \mathbf{a})}_{\text{rewards}} + \gamma \mathbb{E}_{\mathbf{s}' \sim p(\mathbf{s}'|\mathbf{s}, \mathbf{a}), \mathbf{a}' \sim \pi(\mathbf{a}'|\mathbf{s}')} [Q^\pi(\mathbf{s}', \mathbf{a}')] \quad (15.1)$$

Let  $\mathbf{P}^\pi \mathbf{v}$  denote a vector  $\mathbf{w}$  of length  $|S||A|$ :

$$\mathbf{w}(\mathbf{s}, \mathbf{a}) = \mathbb{E}_{\mathbf{s}' \sim p(\mathbf{s}'|\mathbf{s}, \mathbf{a}), \mathbf{a}' \sim \pi(\mathbf{a}'|\mathbf{s}')} [\mathbf{v}(\mathbf{s}', \mathbf{a}')] \quad (15.2)$$

$$\mathbf{w}_{|S||A| \times 1} = \mathbf{P}_{|S||A| \times |S||A|}^\pi \mathbf{v}_{|S||A| \times 1} \quad (15.3)$$

$$Q^\pi = r + \gamma \mathbf{P}^\pi Q^\pi \quad (15.4)$$

$$Q^\pi = (\mathbf{I} - \gamma \mathbf{P}^\pi)^{-1} r \quad (15.5)$$

Let:

- $\phi$  be an  $|S||A| \times N$  feature matrix
  - $\psi$  be an  $|S||A| \times N$  matrix such that  $\psi = (\mathbf{I} - \mathbf{P}^\pi)^{-1}\phi$
  - if  $r = \phi w$ , then  $Q^\pi = \psi w$ , with  $w$  is a  $1 \times N$  row vector  
In other words, if  $r$  is a linear combination of  $\phi$ , then  $Q^\pi$  is a linear combination of  $\psi$
  - $\psi_i$  is a "successor feature" for  $\phi_i$
  - for any new reward function, if we can fit  $r \approx \phi w$ , we get  $Q^\pi \approx \psi w$
- NOTE:** this holds for  $Q^\pi$ , not  $Q^*$

$$Q^*(\mathbf{s}, \mathbf{a}) = r(\mathbf{s}, \mathbf{a}) + \gamma \mathbb{E}_{\mathbf{s}' \sim p(\mathbf{s}'|\mathbf{s}, \mathbf{a})} \left[ \max_{\mathbf{a}'} Q^\pi(\mathbf{s}', \mathbf{a}') \right] \quad (\text{no longer linear})$$

[TODO: ] how to find  $\psi, \phi$  given  $\mathbf{P}^\pi$

**Simplest use:** evaluation

1. get small amount of data  $(\mathbf{s}_i, \mathbf{a}_i, r_i, \mathbf{s}'_i)$  in new MDP
2. fit  $w$  such that  $\phi(\mathbf{s}_i, \mathbf{a}_i)w \approx r_i$  (linear regression)
3. initialize  $Q^\pi(\mathbf{s}, \mathbf{a}) = \psi(\mathbf{s}, \mathbf{a})w$
4. finetune  $\pi$  and  $Q^\pi$  with any RL method

**More sophisticated use:** train multiple  $\psi^{\pi_i}$  functions for different  $\pi_i$

- choose initial policy  $\pi(\mathbf{s}, \mathbf{a}) = \arg \max_{\mathbf{a}} \psi^{\pi_i}(\mathbf{s}, \mathbf{a})w$
- this provides a better initial policy in general

**Additional notes:** successor representations with  $\phi = \mathbf{I} \dots$  [Day93]

# 16 Meta-Learning

[TODO: Read a bit from the begining] Thrun et al. (2012) [TP12].Learning to Learn.

## 16.1 Scaffolding

*Scaffolding* is a term that commonly used in the construction field, but also has a relation to infant's learning process. Scaffolding is a temporary structure that supports the construction, maintenance of a large building ([wiki](#)). In the context of learning, it implies the structured assistance, or guidance, for better accomplishment of new skills and tasks. As the learner's *autonomy* (learning abilities) increases, the support decrease accordingly . [Par; ZBC20]

**Figure 16.1:** Scaffolding in construction.

Extending the idea behind scaffolding to Machine Learning ([ML](#)) and [RL](#): [ZBC20]

- Visual imitation learning [[FYZ+17](#); [SPG19](#)]
- Learning from demonstration [TODO: ]
- Collective learning: learn from / guided by other agents
- Active learning

[TODO: Read [[SSR18](#); [AZ17](#); [BEP+19](#)]]

[TODO: Read [A Generalist Agent](#)]

[TODO: Read [meta](#)]

## 16.2 Learning Resource

- [Learning to learn: An Introduction to Meta Learning](#) || International Conference on Machine Learning (ICML) 2019

### 16.3 Definitions

Conventional supervised learning relies on large and diverse dataset for broad generalization. There are, however, problems with limited labeled data. These scenarios would need a general purpose AI system to adapt and learn on the job.

Mechanistic view	Probabilistic view
<ul style="list-style-type: none"> <li>- Deep neural network model that can read in an entire dataset and make predictions for new datapoints</li> <li>- Training this network uses a meta-dataset, which itself consists of many datasets, each for a different task</li> <li>- Easier to implement meta-learning</li> </ul>	<ul style="list-style-type: none"> <li>- Extract prior information from a set of (meta-training) tasks that allows efficient learning of new tasks</li> <li>- Learning a new task uses this prior and (small) training set to infer most likely posterior parameters</li> <li>- Easier to understand meta-learning</li> </ul>

- If you've learned 100 tasks already, can you figure out how to learn more efficiently?
- Meta-learning = learning to learn
- In practice, very closely related to multi-task
- A meta-learned learner can:
  - Explore more intelligently
  - Avoid trying actions that are known to be useless
  - Acquire the right features more quickly

### 16.4 Supervised Meta-learning

The problem setup (Fig. 16.2):

- Meta-training: acquire your learned learning algorithm
- Meta-testing: use/adapt your learned learning algorithm
- Meta-training and meta-testing have separated training data and test data

Supervised learning:

$$f(x) \rightarrow y$$

$$\arg \max_{\phi} \log p(\phi | \mathcal{D})$$

Supervised meta-learning:

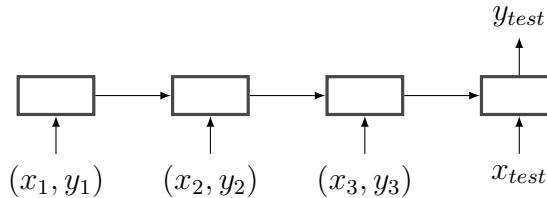

$$f(\mathcal{D}^{tr}, x) \rightarrow y$$

$$\arg \max_{\phi} \log p(\phi | \mathcal{D}, \mathcal{D}_{meta-train})$$

**Figure 16.2:** Supervised meta-learning pipeline (Ravi & Larochelle '17)

$x$	– input
$y$	– output
$\mathcal{D} = \{(x_1, y_1), \dots, (x_k, y_k)\}$	– dataset
$\mathcal{D}_{meta-train} = \{(\mathcal{D}_1^{tr}, \mathcal{D}_1^{ts}), \dots, (\mathcal{D}_n^{tr}, \mathcal{D}_n^{ts})\}$	– meta dataset
$\mathcal{D}_i = \{(x_1^i, y_1^i), \dots, (x_k^i, y_k^i)\}$	

**Figure 16.3:** Using RNN to input a training set  $\mathcal{D}^{tr}$ , instead of just  $x$ .

The knowledge from the meta training dataset  $\mathcal{D}_{meta-train}$  is extracted into parameter  $\theta$ :

$$\theta^* = \arg \max_{\theta} \log p(\theta | \mathcal{D}_{meta-train}) \quad - \text{meta-learning} \quad (16.1)$$

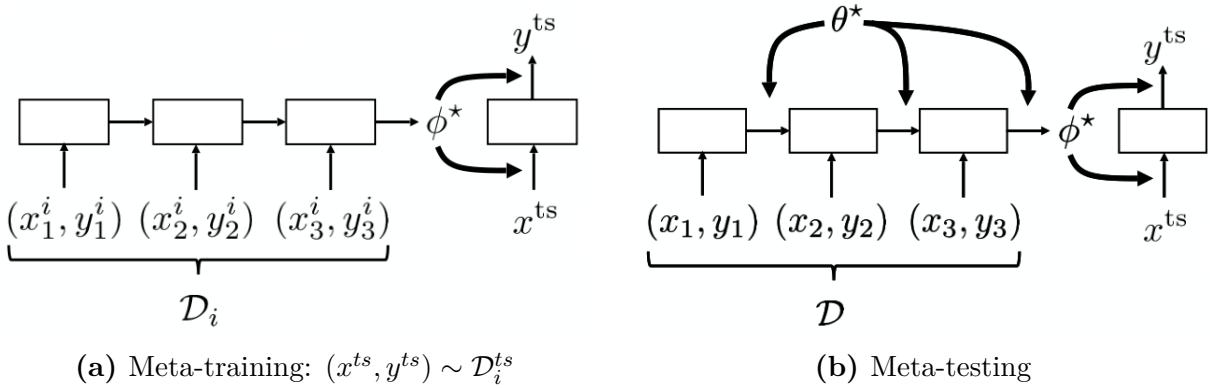

$$\log p(\phi | \mathcal{D}, \mathcal{D}_{meta-train}) \approx \log p(\phi | \mathcal{D}, \theta^*) \quad (16.2)$$

$$\phi^* = \arg \max_{\phi} \log p(\phi | \mathcal{D}, \theta^*) \quad - \text{adaptation} \quad (16.3)$$

$$\phi^* = f_{\theta^*}(\mathcal{D}^{tr}) \quad (16.4)$$

[TODO: still confusing]

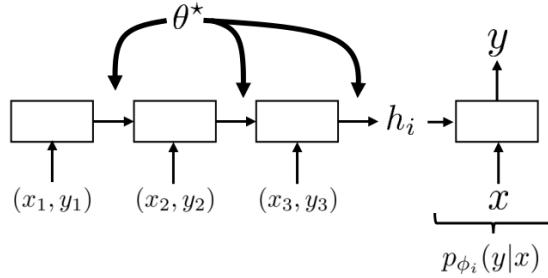

- In meta-training, each task has a training set  $\mathcal{D}_i^{tr}$  and a test set  $\mathcal{D}_i^{ts}$ .
- $\phi_i$  is the **params.** learned from the task's training set  $\mathcal{D}_i^{tr}$  (Fig. 16.5).
- $\phi_i = [h_i, \theta_p]$  with  $h_i$  - RNN hidden state,  $\theta_p$  - meta-learned weights.

**Figure 16.4:** Matching test and train conditions.

- In meta-testing, we optimize  $\theta$ , which is the arg min of the average over all the tasks (in meta-training), of the loss of that task on its test set  $\mathcal{D}_i^{ts}$ .

**NOTE:** The test set in meta-testing is not available (of course) for learning  $\theta$ , but the test set for meta-training is (Fig. 16.2).

**Figure 16.5:**  $\phi_i = [h_i, \theta_p]$  ([src](#))

## 16.5 Meta Reinforcement Learning

Reinforcement learning:

$$\begin{aligned} \theta^* &= \arg \min_{\theta} \mathbb{E}_{\pi_{\theta}(\tau)}[R(\tau)] \\ &= f_{RL}(\mathcal{M}) \end{aligned}$$

$\mathcal{M} = \{\mathcal{S}, \mathcal{A}, \mathcal{P}, r\}$ : the MDP

Meta-reinforcement learning:

$$\begin{aligned} \theta^* &= \arg \min_{\theta} \sum_{i=1}^n \mathbb{E}_{\pi_{\phi_i}(\tau)}[R(\tau)] \\ &\text{where } \phi_i = f_{\theta}(\mathcal{M}_i) \\ &\mathcal{M}_i : \text{the MDP for task } i \end{aligned}$$

$$\mathcal{M}_i \sim p(\mathcal{M}) \tag{16.5}$$

$$\mathcal{M}_{test} \sim p(\mathcal{M}) \tag{16.6}$$

- In multi-task RL, the context is typically given.
- In meta-RL, the *context* is inferred from experience from  $\mathcal{M}_i$ :  $\pi_{\theta}(a_t | s_t, \phi_i)$

## 16.6 Gradient-based Meta Learning

**NOTE:** The word *agnostic* implies that some characteristics are irrelevant and that something is widely applicable. E.g., a pick and place strategy is object-agnostic, if it doesn't matter what characteristics the object has, classes, geometries, materials, etc. In other words, that strategy is compatible to a variety of objects.

**Idea:** pretraining as a type of meta-learning.

In Model-Agnostic Meta-Learning ([MAML](#)),  $f_\theta(\mathcal{M}_i)$  is itself an [RL algor.](#) [[FAL17](#)]

$$\theta^* = \arg \max \sum_{i=1}^n \mathbb{E}_{\pi_{\theta_i}} [r(\tau)] \quad (16.7)$$

$$\text{where } \phi_i = f_\theta(\mathcal{M}_i) \quad (16.8)$$

$$f_\theta(\mathcal{M}_i) = \theta + \alpha \nabla_\theta J_i(\theta) \quad (16.9)$$

$$\theta \leftarrow \theta + \alpha \nabla_\theta J(\theta) \quad (16.10)$$

$$\theta \leftarrow \theta + \beta \sum_i \nabla_\theta J_i[\theta + \alpha \nabla_\theta J(\theta)] \quad (16.11)$$

## 16.7 Meta-RL as a POMDP

### 16.7.1 PEARL

### 16.7.2 MELD

## 16.8 Model-Based Meta-RL

## 16.9 Meta-RL and Emergent Phenomena

Humans and animals learn behaviors in a variety of ways. Perhaps each is a separate algorithm in the brain. But maybe these are all emergent phenomena resulting from meta-[RL](#):

- Highly efficient but (apparently) model-free RL
- Episodic recall
- Model-based RL
- Causal inference
- etc.

# 18 Goal-based RL

All human and robot's actions follow a certain goal. Goal tracking is as old as target tracking in control engineering [McD92]. However, in many cases, the robot is programmed to follow a hidden goal inside the mind of the engineers. In other words, the robots or agents do not aware of the existence of the goals. They do, however, receive cues, usually in the form of cost functions, whether the goals is close or not. A more proactive learning approach would be to explicitly let the robots know of the goals while learning.

Goal-conditioned learning provides a harder, but more general problem setting. Instead of communicating *how* to perform a single task, we communicate only *what* needs to be done by providing the goals, which can be the desired observations of world states (single data point or a sparse/dense sequence of data). Given the goal, the agent is required to infer how to perform the task by itself. In psychology, this is known as *observational learning* [BW77]. The task might not be finished in an optimal way, but sometimes it's more important that the task is completed. In addition, it's easier for the expert to demonstrate multiple tasks quickly and easily. [PML+18]

Two helpful literature surveys:

- Liu et al. (2022) [LZZ22]. “*Goal-Conditioned Reinforcement Learning: Problems and Solutions*”.
- Colas et al. (2022) [CKS+22]. “*Autotelic Agents with Intrinsically Motivated Goal-Conditioned Reinforcement Learning: A Short Survey*”.

## 18.1 Introduction

A goal is similar to *terminal-reward function*  $z : \mathcal{S} \rightarrow \mathbb{R}$ , which is the reward received if termination occurs at state  $s$  [SMD+11]. Early work has proposed policy and value network conditioned on different goals. [SHG+15]

$$g \in \mathcal{G} \quad \text{space of possible goal } \mathcal{G} \tag{18.1}$$

$$m_g : \mathcal{S} \rightarrow \mathcal{G} \quad \text{mapping from state space to goal space} \tag{18.2}$$

$$u_g : \mathcal{S} \times \mathcal{A} \rightarrow \mathbb{R} \quad \text{goal-conditioned reward function} \tag{18.3}$$

$$\pi : \mathcal{S} \times \mathcal{G} \rightarrow \mathcal{A} \quad \text{goal-conditioned policy} \tag{18.4}$$

$$Q_\pi(s_t, a_t, g) = \mathbb{E}_\pi[r_t | s_t, a_t, g] \quad \text{goal-conditioned Q function} \tag{18.5}$$

Comparing to other conventional [RL](#) approaches, goal-conditioned learning has various nice properties:

- Off-policy learning
- Can be trained in a self-supervised / unsupervised manner for environment exploration
- Multi-task learning, [a.k.a.](#) multi-goal learning
- Works well with sparse and binary reward.
- Has an implicit curriculum / can be extend to curriculum learning

## 18.2 Reward Shaping

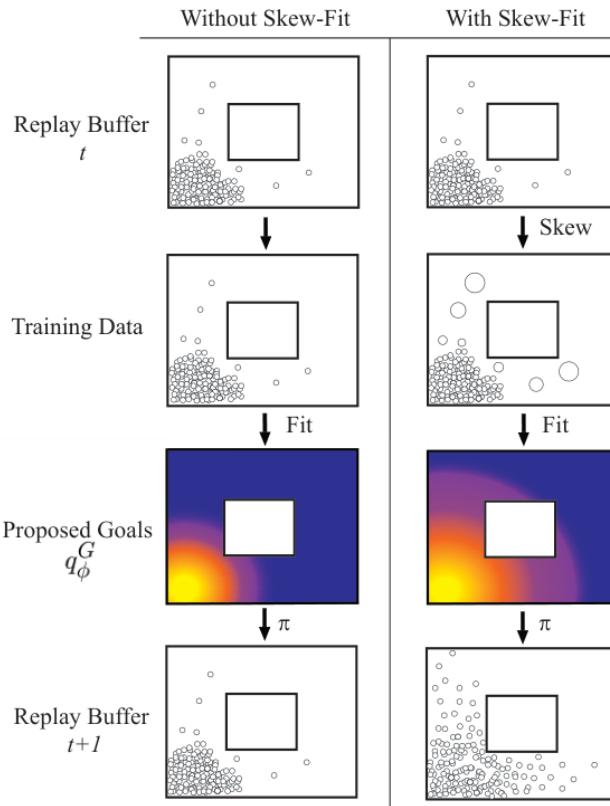

Reward is basically the dopamine of [RL](#). It's the feedback from the environment that let the model know which are the desired behaviors to be enforced. Reward shaping is the step in which we design the reward function for our [MDP](#). Most of the time, it is complicate and requires domain knowledge. Inverse [RL](#) is another direction to learn complex reward function from expert's demonstration. Goal-conditioned learning provides an elegant and easy way to tackle reward shaping. The example is the Hindsight Experience Replay ([HER](#)), a goal-conditioned [RL](#) framework for problems with sparse and binary reward [[AWR+17](#)].

- Normally, the transitions  $(\mathbf{s}, \mathbf{a}, \mathbf{s}', r)_i$  is added to the buffer
- [HER](#) adds the transition with both desired and actually reached goals:
  - $(\mathbf{s}, \mathbf{a}, \mathbf{s}', g_{desired}, -1)_i$ . Since the desired goal is not reached, the reward is  $r = -1$ (or 0)
  - $(\mathbf{s}, \mathbf{a}, \mathbf{s}', g_{actual}, 1)_i$ . The transition with actual goal has positive binary reward  $r = 1$
- Add some exploration, even more than count-based exploration
- Reward shaping may help, and it may not.
- **NOTE:** Successful applications of [RL](#) to difficult manipulation tasks which does not use demonstrations usually have more complicated reward functions (e.g. [[PHL+17](#)]).
  - There is a huge discrepancy between what we optimize and the success condition
  - Shaped rewards penalize for inappropriate behavior which may hinder exploration.
- Experiments compare performances of actor-critic (DDPG) [[LHP+15](#)] and Deep Q-networks (DQN) [[MKS+15](#)] with and without [HER](#)

## 18.3 Exploration

The process of trying to reach different goals is equivalent with going to different states, which is exactly what exploration is about. Thus the more diverse and also gradually more challenging the goals are, the better the exploration scheme is. The goal can be sampled from:

- the actual trajectories [AWR+17].
  - the complete distribution of the goals, which then it's required to learn that distribution.
- In [NPD+18], Nair et al. combine that with TD3 [FHM18] (model-free Q-learning), with the reward as the negative Mahalanobis distance between the latent vectors of the goal and of the current state.
- Additional extension on the fact that the initial policy might stuck in local optima, which results in similar visited states. The goal/state distribution can be modified to prioritize less visited goals/states [PDL+19]

**Figure 18.1:** Skewing the goal/state distribution to sample less visited ones. [PDL+19]

## 18.4 Curriculum Learning

Curriculum Learning is about how to gradually increase how challenging the goal is.

- HER's extension: Curriculum-guided HER [FZD+19]

## 18.5 Sample Efficiency

So far, compared to approaches not conditioned on the goals, most experiments of goal-conditioned learning also showed better sample efficiency when dealing with complex tasks. [AWR+17;

NPD+18]

## 18.6 Learning Sequence of Subgoals

Complex actions are sequence of more simple actions. E.g.:

- Pouring a cup of water: grasp the bottle, move it above the cup, in-place rotate, put the bottle back.
- Make a cup of coffee: grasp the cup, move it to the coffee machine, put it in specified position, press the machine button [SDZ+19]

One could certainly explicitly specify the subgoals / instructions for the robot to learn, either giving goal after goals, or pre-recording a (dense/sparse) sequence of subgoals [PML+18; SDZ+19]. However, there exists more elaborate schemes.

### 18.6.1 Imagined Subgoals

With the assumption that the goal space is the state space  $\mathcal{G} \equiv \mathcal{S}$ , additional to an actor-critic model, a high-level policy  $\pi^H(\cdot|s, g)$  predicts subgoals  $s_g$  [CSSL21]

- Using value function  $V^\pi(s, g)$  to estimate the distance between valid states, define the subgoal  $s_g$  as midpoints on the path from  $s$  to  $g$ . Minimize the cost:

$$C_\pi(s_g|s, g) = \max(V^\pi(s, s_g), V^\pi(s_g, g)) \quad (18.6)$$

- Enforce subgoal as valid state by KL-divergence with actual valid state distribution  $p_s(\cdot)$

$$D_{KL}(\pi^H(\cdot|s, g) \parallel p_s(\cdot)) \leq \epsilon \quad (18.7)$$

- Policy of reaching final goal should be similar to reaching subgoals

$$D_{KL}(\pi(\cdot|s, g) \parallel \pi(\cdot|s, s_g)) \leq \epsilon \quad (18.8)$$

### 18.6.2 Learning from YouTube Videos

Some proposals to model action plans using symbolic representation:  $Action(Object_1, Object_2, \dots)$

- Zhang et al. (2019) [ZN19]. “Robot learning and execution of collaborative manipulation plans from YouTube cooking videos”.
- Yang et al. (2015) [YLF+15]. “Robot Learning Manipulation Action Plans by Watching Unconstrained Videos from the World Wide Web”.

Action plans as symbolic representation with visual sentence, e.g., *Grasp\_PoS(LeftHand, Spatula)*, *Action\_Stir(Spatula, Bowl)*

## 18.7 Tips and Tricks

- Have a library of simple action primitives (in some problem settings, there is only 1 primitive). The model chooses an action from that library and/or output [params](#). (as regression task) for that action primitive. [PML+18]  
Direct control leads to shaking artifacts in movements (e.g., [video1](#), [video2](#)) [NPD+18]
- Whether how the task is finished is important
  - If NOT: consider forward consistency loss [PML+18]
  - If YES: ?
- Model & loss function:
  - Binary reward [AWR+17]
  - L2 loss in feature space? [NPD+18; PML+18]

## 18.8 Experiments

### 18.8.1 RL Algorithms

- Imitation learning [PML+18]
- Actor-critic
  - DDPG [AWR+17]
  - [CSSL21]
- Value-based RL
  - DQN [AWR+17; NPD+18]

### 18.8.2 Robotic Tasks

- Simple reaching task
- Object grasping/manipulation
  - Object grasping [AWR+17; NPD+18]
  - Object pushing [AWR+17; NPD+18; CSSL21]
  - Rope manipulation [PML+18]
  - Door opening [NPD+18]
- 2D/3D mobile robot navigation [PML+18; CSSL21]

# 19 RL for Robotics

## 19.1 Motor Primitive Policy

Not the same as path primitive from robotic trajectory planning. [INS02]. Motor plans are trajectory plans for each degrees of freedom (DOF):

- Spline-based trajectory plans: the desired movement is parameterized by its spline nodes and the duration of each spline node. [MGG+95; SKK08]
- Nonlinear dynamic motor primitives: the movement plans  $(q_d, \dot{q}_d)$  are represented in terms of the time evolution of the nonlinear dynamical systems [INS02]

$$\ddot{q}_d = f(q_d, z, g, \tau, \theta) \quad \text{in which:}$$

$(q_d, \dot{q}_d)$	– the desired position and velocity profile of a joint
$z$	– the internal state $\ddot{z} = f_c(z, \tau)$
$\theta$	– params. for $f$
$\tau$	– the time duration shared by all DOFs

We include exploration by adding a small perturbation to the desired accelerations

$$\epsilon \sim \mathcal{N}(0, \sigma^2) \quad \text{– small perturbation} \quad (19.1)$$

$$\ddot{\tilde{q}}_d = \ddot{q}_d + \epsilon \quad \text{– the perturbed target output} \quad (19.2)$$

$$\pi(\ddot{\tilde{q}}_d | \ddot{q}_d) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(\ddot{\tilde{q}}_d - \ddot{q}_d)^2}{2\sigma^2}\right) \quad \text{– a stochastic policy} \quad (19.3)$$

## 19.2 Requirements

Requirements for motor primitive learning in robotics: [PS08]

- Any change to the policy parameterization has to be smooth, because
  - drastic changes can be hazardous for the robot and its environment
  - rendering initialization of the policy based on domain knowledge or imitation learning useless, as these would otherwise vanish after a single update step due to out-of-distribution problem [Sch96].
- Need to guarantee that the policy is improved in the update steps at least on average. This rules out greedy value function based methods with approximated value functions, as these methods are frequently problematic in regard of this property [Kak03]

Multi-task transfer learning: deeper explanation for gradient interference and winner-take-all problem

## 20.2 Reproducibility

Checklist [Pin18]:

For all **algorithms** presented, check if you include:

- A clear description of the algorithm.
- An analysis of the complexity (time, space, sample size) of the algorithm.
- A link to downloadable source code, including all dependencies.

For any **theoretical claim**, check if you include:

- A statement of the result.
- A clear explanation of any assumptions.
- A complete proof of the claim.

For all **figures and tables** that present empirical results, check if you include:

- A complete description of the data collection process, including sample size.
- A link to downloadable version of the dataset or simulation environment.
- An explanation of how samples were allocated for training / validation / testing.
- An explanation of any data that was excluded.
- The range of hyper-parameters considered, method to select the best hyper-parameter configuration, and specification of all hyper-parameters used to generate results.
- The exact number of evaluation runs.
- A description of how experiments were run.
- A clear definition of the specific measure or statistics used to report results.
- Clearly defined error bars.

- A description of results including central tendency (e.g. mean) and variation (e.g. stddev).
- The computing infrastructure used.

## 20.3 Stability

### 20.3.1 Problem

- Devising stable RL algorithms is very hard
- Q-learning/value function estimation
  - Fitted Q/fitted value methods with deep network function estimators are typically not contractions, hence no guarantee of convergence
  - Lots of parameters for stability: target network delay, replay buffer size, clipping, sensitivity to learning rates, etc.
- Policy gradient/lielihood ratio/REINFORCE
  - Very high variance gradient estimator
  - Lots of samples, complex baselines, etc.
  - Parameters: batch size, learning rate, design of baseline
- Model-based RL algorithms
  - Model class and fitting method
  - Optimizing policy w.r.t. model non-trivial due to back-propagation
  - More subtle issue: policy tends to exploit the model
- How representative is your simulator? Usually the answer is "not very"

### 20.3.2 Directions

Can we develop more stable algorithms that are less sensitive to hyperparameters?

- Algorithms with favorable improvement and convergence properties
  - Trust region policy optimization [SLA+15]
  - Safe RL, high-confidence policy improvement
- Algorithms that adaptively adjust parameters
  - Q-Prop: Sample-efficient policy gradient with an off-policy critic [GLG+16]

## 20.4 Sample Complexity

### 20.4.1 Problem

Efficiency: how long does it take to converge? (how many samples)

- Real-world learning becomes difficult or impractical
- Precludes the use of expensive, high-fidelity simulators
- Limits applicability to real-world problems

[Irp18]

#### 20.4.2 Directions

- Better model-based RL algorithms
- Design faster algorithms
  - Addressing Function Approximation Error in Actor-Critic Algorithms [FHM18]
  - Soft Actor-Critic [HZA+18]
- Reuse prior knowledge to accelerate reinforcement learning
  - RL2: Fast reinforcement learning via slow reinforcement learning [DSC+16]
  - Learning to reinforcement learning [WKNT+16]
  - Model-agnostic meta-learning [FAL17]
  - DREAM [LRL+20]

### 20.5 Scaling and Generalization

Off-policy and Offline RL

### 20.6 Problem Formulation

#### 20.6.1 Single Task or Multi-Task

We have the assumption that the trained tasks and the test task are from the same distribution. As the result, with enough trials, the agent will visit every possible situations. But in real world, it's never like that.

Prior works on generalizing from multi-task learning:

- Train on multiple tasks, then try to generalize or finetune
  - Policy distillation [RCG+15]
  - Actor-mimic [PBS15]
  - Model-agnostic meta-learning [FAL17]
- Unsupervised or weakly supervised learning of diverse behaviors
  - Stochastic neural networks [FDA17]

- Reinforcement learning with deep energy-based policies [HTA+17]
- Unsupervised information-theoretic exploration

### 20.6.2 Supervision

$$\begin{aligned}
 r(b_z^{(1)}, s^P, s^{B1}, s^{B2}) &= \begin{cases} 1 & \text{if } \text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0 & \text{otherwise} \end{cases} \\
 r(b_z^{(1)}, s^P, s^{B1}, s^{B2}) &= \begin{cases} 1 & \text{if } \text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0.25 & \text{if } \neg\text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \wedge \text{grasp}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0 & \text{otherwise} \end{cases} \\
 r(b_z^{(1)}, s^P, s^{B1}, s^{B2}) &= \begin{cases} 1 & \text{if } \text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0.25 & \text{if } \neg\text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \wedge \text{grasp}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0.125 & \text{if } \neg(\text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \vee \text{grasp}(b_z^{(1)}, s^P, s^{B1}, s^{B2})) \wedge \text{reach}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0 & \text{otherwise} \end{cases} \\
 r(b_z^{(1)}, s^P, s^{B1}, s^{B2}) &= \begin{cases} 1 & \text{if } \text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0.25 + 0.25r_{S2}(s^{B1}, s^P) & \text{if } \neg\text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \wedge \text{grasp}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0.125 & \text{if } \neg(\text{stack}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \vee \text{grasp}(b_z^{(1)}, s^P, s^{B1}, s^{B2})) \wedge \text{reach}(b_z^{(1)}, s^P, s^{B1}, s^{B2}) \\ 0 + 0.125r_{S1}(s^{B1}, s^P) & \text{otherwise} \end{cases}
 \end{aligned}$$

**Figure 20.1:** Complex reward function [PHL+17]

- If you want to learn from many different tasks, you need to get those tasks somewhere!
- Supervision comes from reward.
- Learn objectives/rewards from demonstration (inverse RL)
- Generate objectives automatically?

### Unsupervised RL

- Interact with the world, without a reward function
- Learn something about the world (what?)
- Use what you learned to quickly solve new tasks

# 21 Technical Tools

This chapter talks about or at least lists out helpful tools, platforms for working with [RL](#)

## 21.1 Supporting Platforms & Tools

Supporting platforms for simulation

- MuJoCo
- [OpenAI Gym](#): is a standard API for [RL](#), and a diverse collection of reference environments.
- [PyBullet](#): physics simulation for games, visual effects, robotics and [RL](#).

## 21.2 Coding Libraries

- [Acme](#): DeepMind's research framework for [RL](#)
- [TensorFlow Agents](#)
- [OpenAI Baselines](#): is a set of high-quality implementations of [RL](#) algorithms.

## 22 Tips and Tricks

Check:

- [Pin18]

# 23 Research Proposal

One major challenge in **RL** is the ability to generalize to different tasks. For **CV** with supervised learning, a model can be trained on a large dataset (e.g., ImageNet), then retrained on a smaller dataset to adapt with a specific task. This is possible because it was proven that early layers manage to learn different feature representations from the image. Thus, the feature extraction and inference process (based on that feature learning) can be separated. It is uncertain though, what a **RL** model manages to learn in early layers.

What **RL** differs from more conventional supervised learning are large diverse dataset, training procedure, how and when the data is collected, etc. There are various proposed solution for **RL** generalization problem: transfer learning, multi-task learning, meta-**RL**. Offline **RL** is one of those. It's strange though, as offline **RL** aims to limit the interaction between the model and the world. Yet this interaction is what differs **RL** with other **AI** algorithms.

## 23.1 Goal-oriented RL

Why the dataset is packed in the way transitions goes with rewards  $\mathcal{D} = \{(\mathbf{s}_i, \mathbf{a}_i, \mathbf{s}'_i, r_i)\}$ . Prior works on single task have an underlying goal, from that goal, we have rewards for each state-action transition in the dataset. With different tasks, the rewards should be different, should the transition then goes with a certain goal. This is obvious in the multi-task setting. But even for single task setting, it's a bit strange because human's actions aren't often based on maximize rewards (keep running as far as we can, etc.). Even in business, we divide to quarterly objectives. Is it weird, even with discount factor or constrained reward windows?  $\Rightarrow$  conditional **RL** or task-oriented **RL**. What if we remove the reward completely and just decide our actions based on desired goal and current state?

completely removing the reward is also the core idea behind imagined-goal-based exploration strategy, etc. But what if we apply this idea to common **RL** training and testing

### NOTE:

- The reward can be seen as a representation for the goal.
- Eliminate all problems with value functions (overconfidence, etc.)
- Having a natural extension to multi-task learning

### 23.1.1 Goal-oriented Imitation Learning

A policy  $\pi_\theta$  that is conditional on the goal  $g$ , take in state  $s$  and output action  $a$  (preferably joint configurations). The policy is optimized to copy the expert behaviors

$$\pi_\theta(a|s, g) \quad (23.1)$$

### 23.1.2 Goal-oriented RL

Same as above, but the policy is optimized not by maximize the reward, but by how far / different the goal state is, from the current state.

The prior reward is basically a representation of how different the goal state from the current state.

Would these solve the instability, overestimation problem of value-based [RL](#) approaches?

### 23.1.3 CGAN

Conditional Generative Adversarial Network ([CGAN](#)) idea:

- Generator:  $\mathbf{a} = G(\mathbf{s}|g)$
- Discriminator:  $D(\mathbf{s}, \mathbf{a}, g) = \text{good/bad?}$

[TODO: How is this relates to the notion of "*context*" in the literature?]

## 23.2 Connection with Psychology

### 23.2.1 Classical Conditioning

The Pavlov conditioning: the experiment on dogs has shown conditioned response ([CR](#))s simply adapt to conditioned stimuli ([CS](#)). Single task learning perhaps fail to generalize and might lead to overfitting probably because it is just an over-adaptation of the neural network to that single task.

### 23.2.2 Blocking conditioning

- Experiment 1: CS1 and unconditioned stimuli (US) lead to CR
- Experiment 2: CS2 then CS1 and US lead to CR
- Experiment 3: CS2 alone doesn't lead to CR

The Rescorla–Wagner model (Rescorla and Wagner, 1972) offer an influential explanation for blocking

### 23.2.3 High-order Conditioning

- Experiment 1: CS1 and US lead to CR
- Experiment 2: CS2 leads to CS1
- Experiment 3: CS2 leads to CR

## 23.3 Connection with Neuroscience
